## Results from OPERA

- $\nu$  oscillation
- $\nu$  time-of-flight

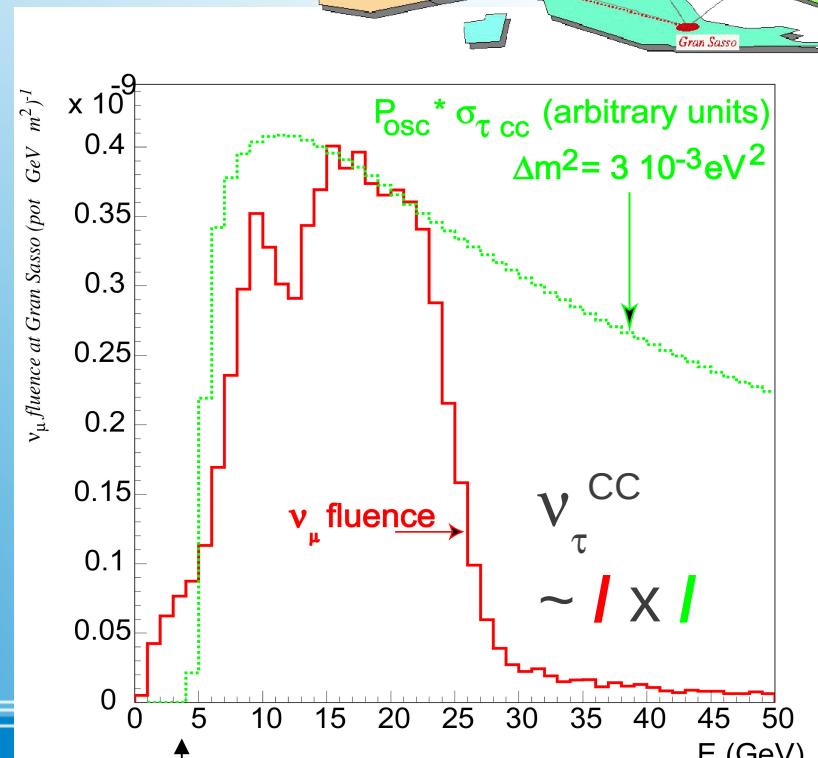

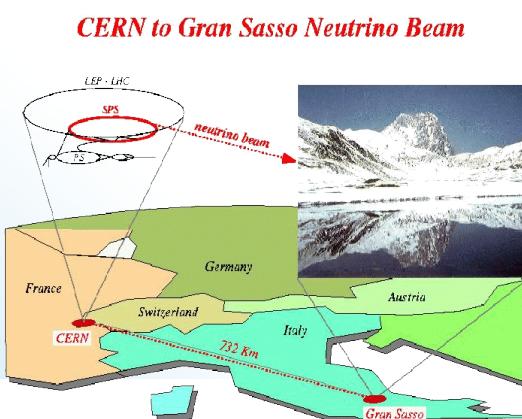

# Goal: direct detection of $\nu_\mu \rightarrow \nu_\tau$ neutrino oscillation in appearance mode

## Requirements:

- 1) high neutrino energy ( $\tau$  cross section)
- 1) long baseline (atmospheric  $\Delta m^2$ )
- 3) high beam intensity ( $L=730$  km) + large mass
- 5) exceptional granularity to detect the short lived  $\tau$  leptons

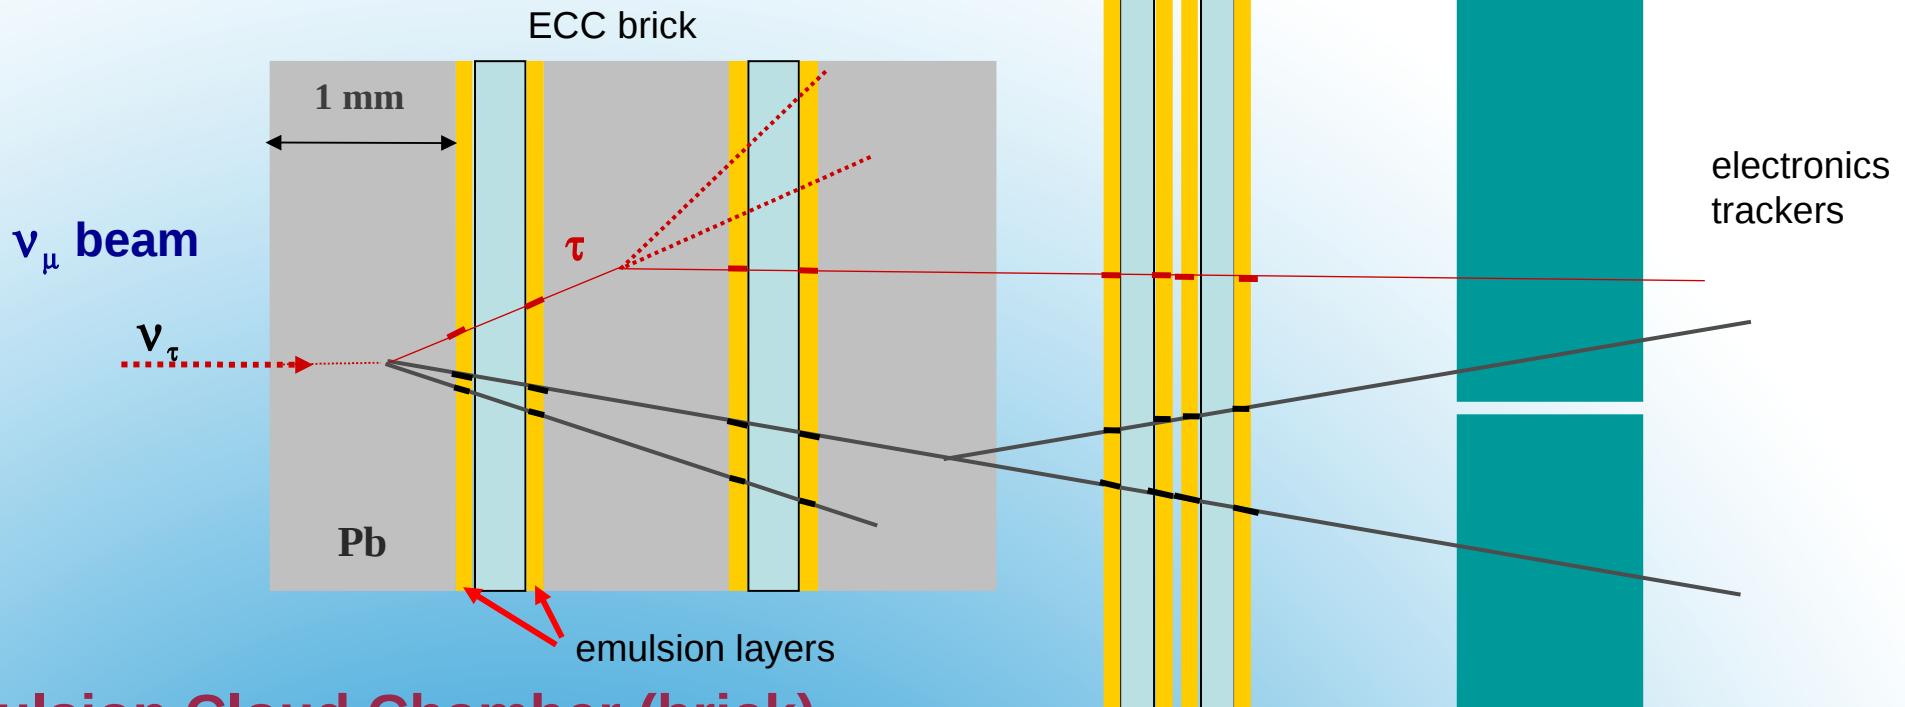

$$\nu_\mu \rightarrow \nu_\tau$$

$22.5 \times 10^{19}$  pot  
 $23600 \nu_\mu$  CC+NC  
 $520 \bar{\nu}_\mu$  CC+NC  
 $160 \nu_e + \bar{\nu}_e$  CC  
 $115 \nu_\tau$  CC

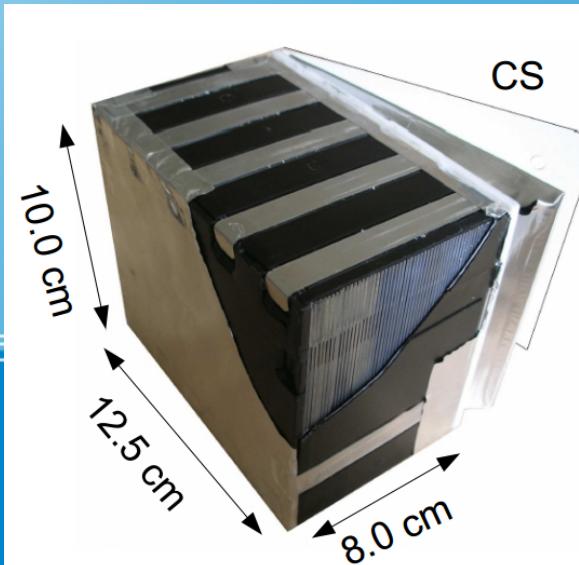

$\tau$  threshold  $\sim 3.5$  GeV, slow rise

$$[(m_\tau + m_p)^2 - m_p^2] / 2m_p$$

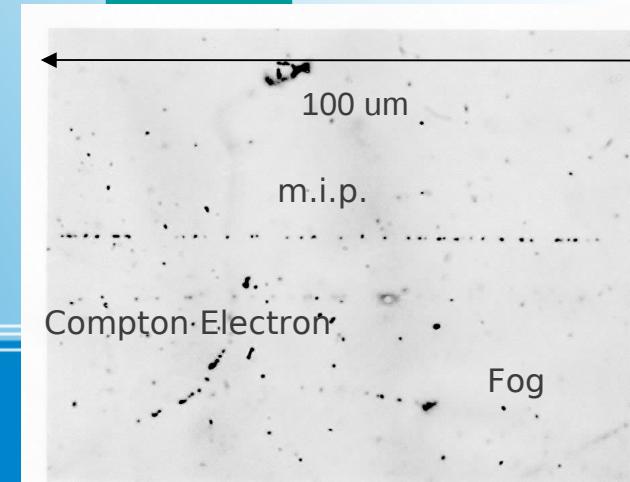

## Emulsion Cloud Chamber (brick)

interface films (CS)

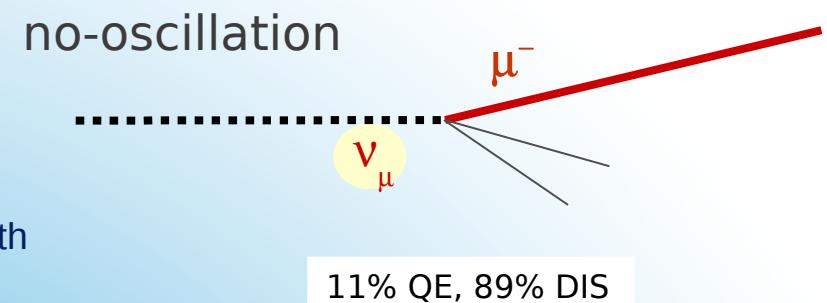

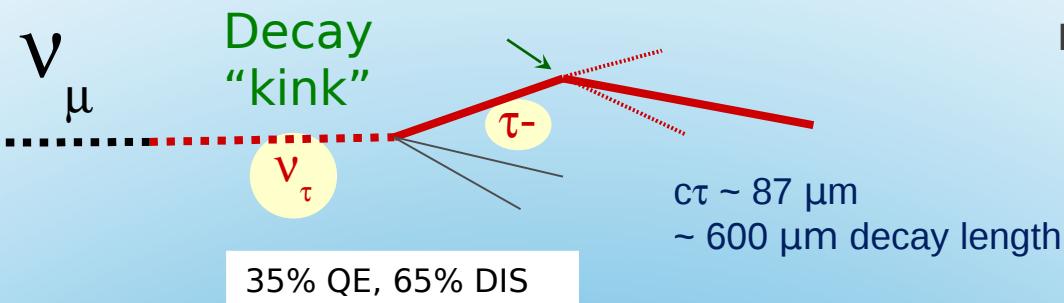

57+56 emulsion (300um)+lead(1mm) plates  
 External removable doublet (CS)  
 150000 units in total (8.3 kg each). 1.25 kton  
 Position: 1 um, slope: 2 mrad at single plate  
 e.m. calorimetry:  $\sigma/E = 40\%/\sqrt{E}$   
 MCS:  $\Delta p/p < 0.2$  after  $5 X^0$  up to 4 GeV

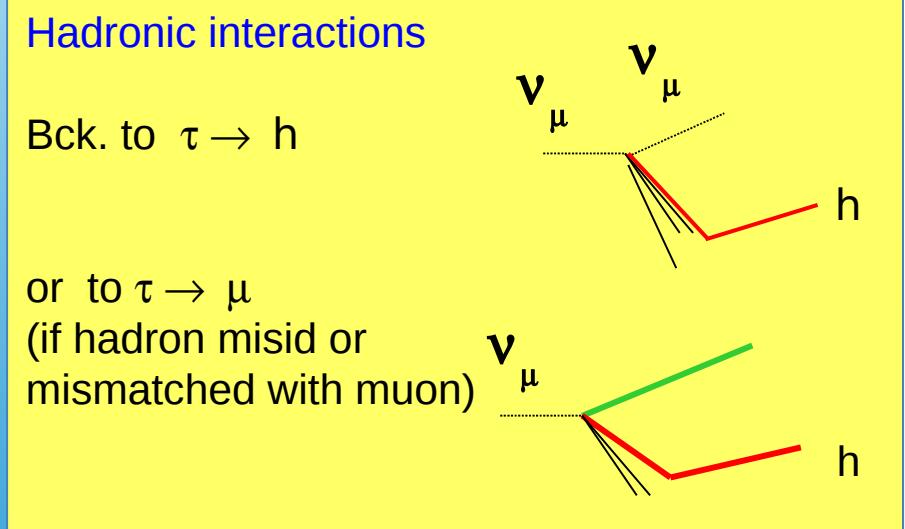

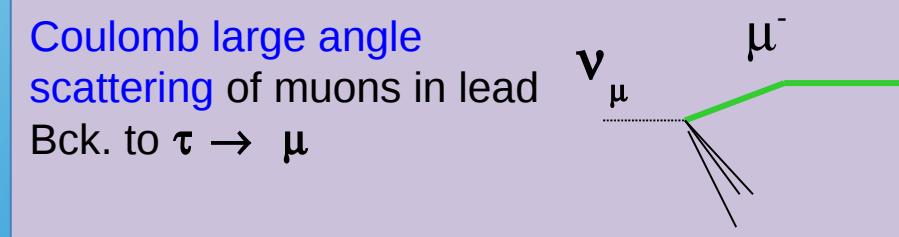

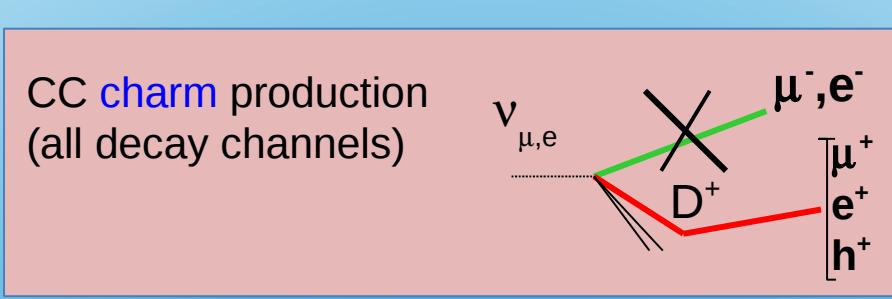

# Conceptual design

# Separation of $\nu_\tau$ CC from the dominant $\nu_\mu$ interactions:

## event-by-event identification of the peculiar $\tau$ decay topology

## Backgrounds

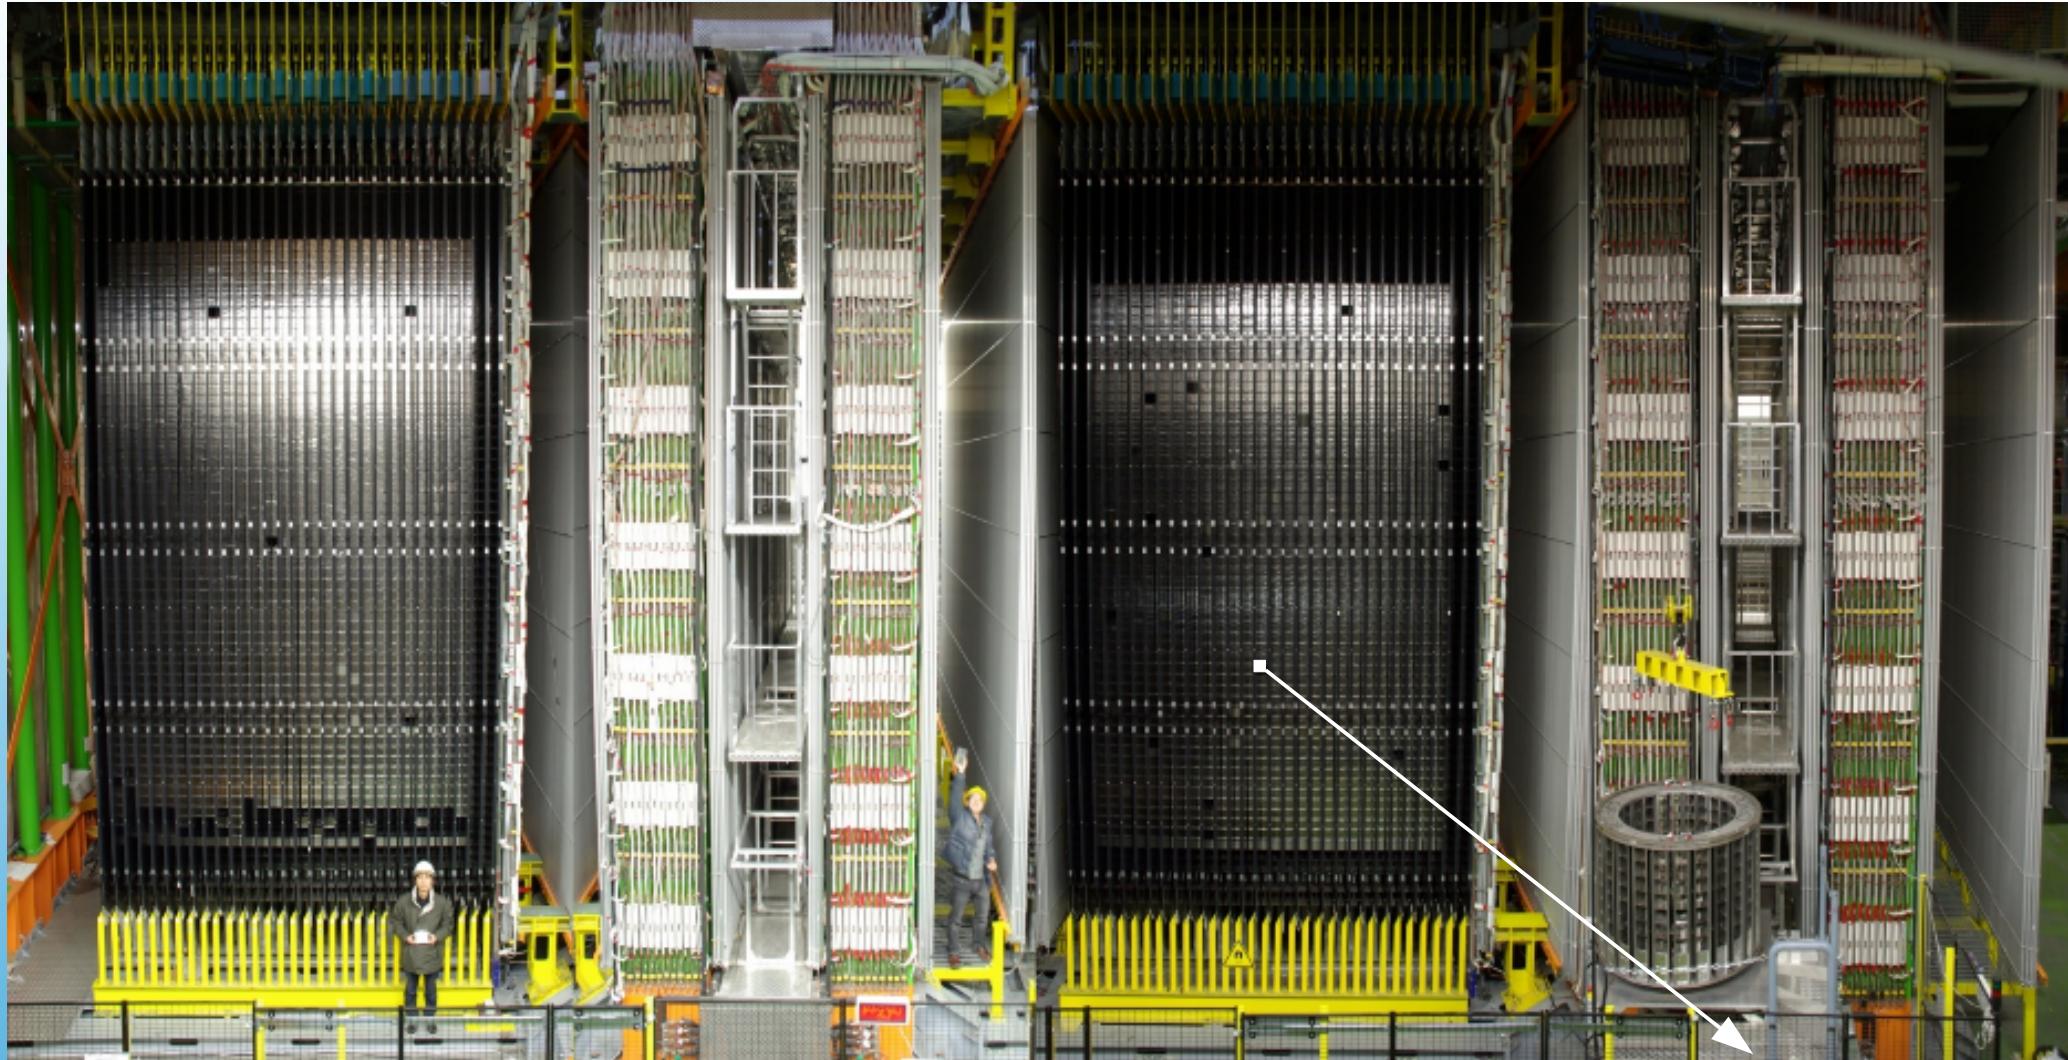

## $\nu_\tau$ detection

Super Module 1

Super Module 2

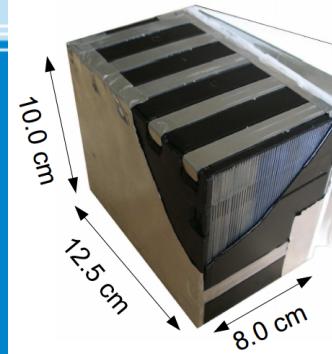

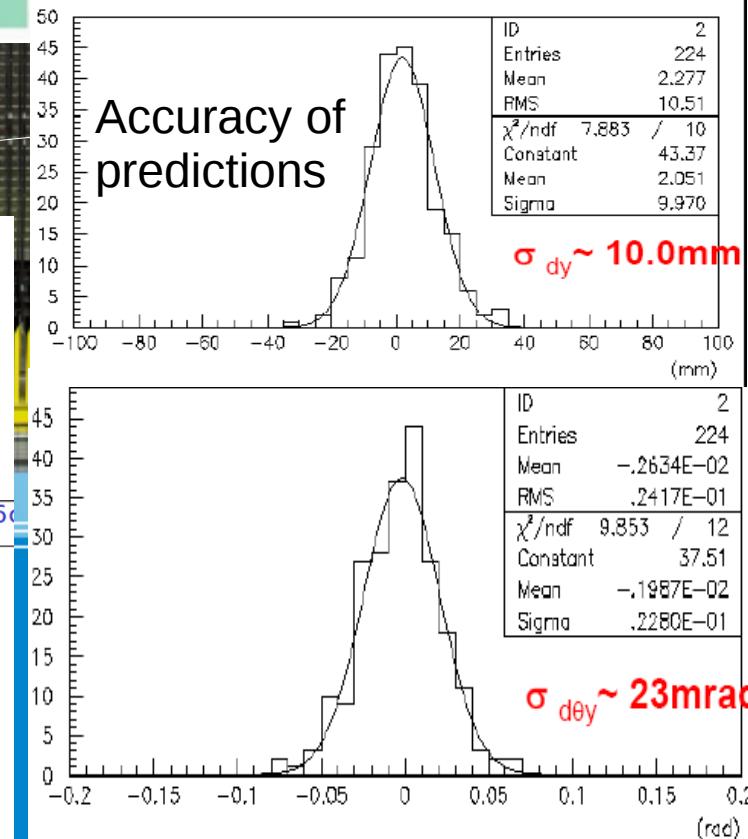

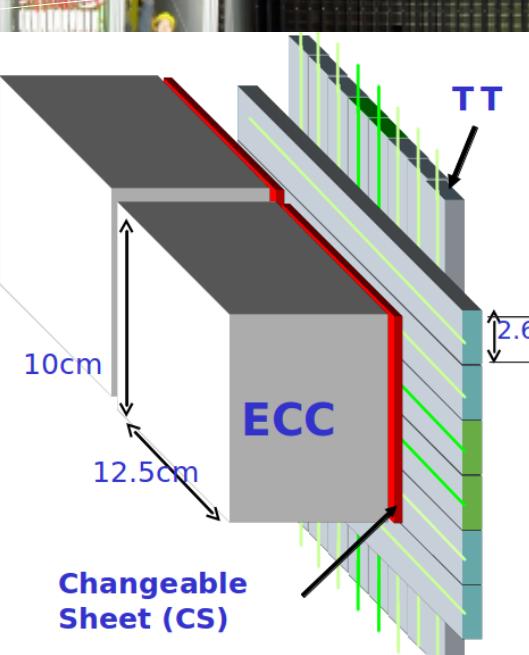

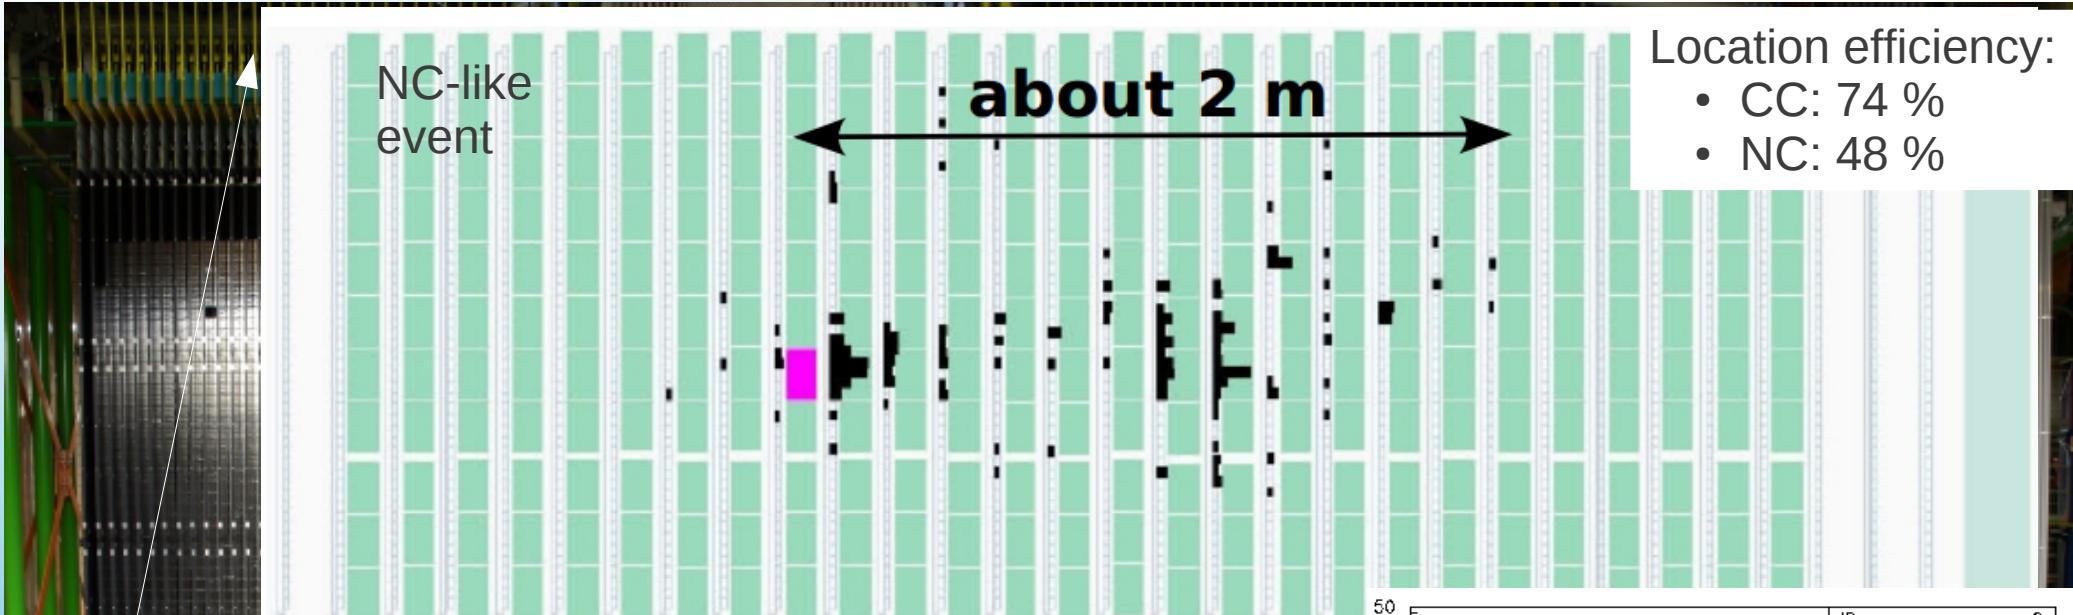

Target area

$\mu$  spectrometer

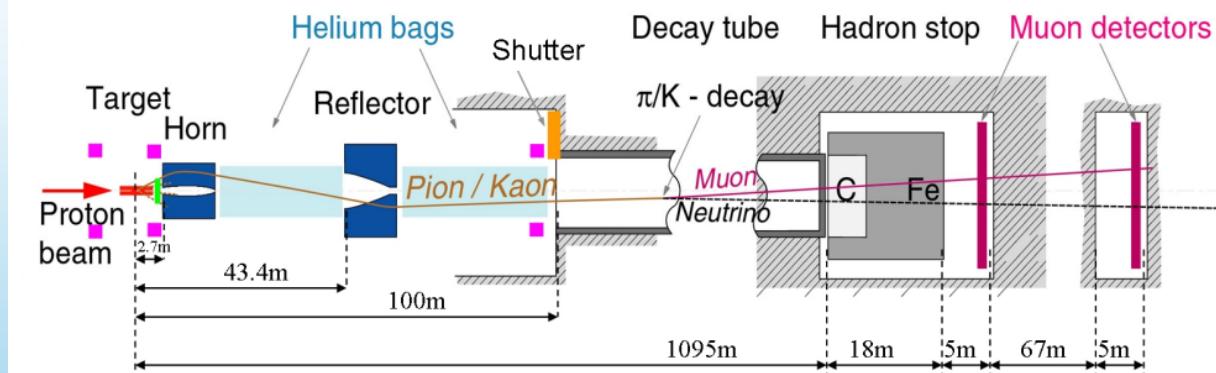

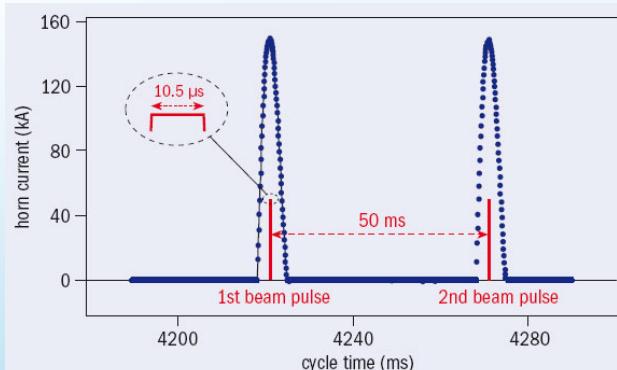

150000 units in total. 1.25 kton

# The detector

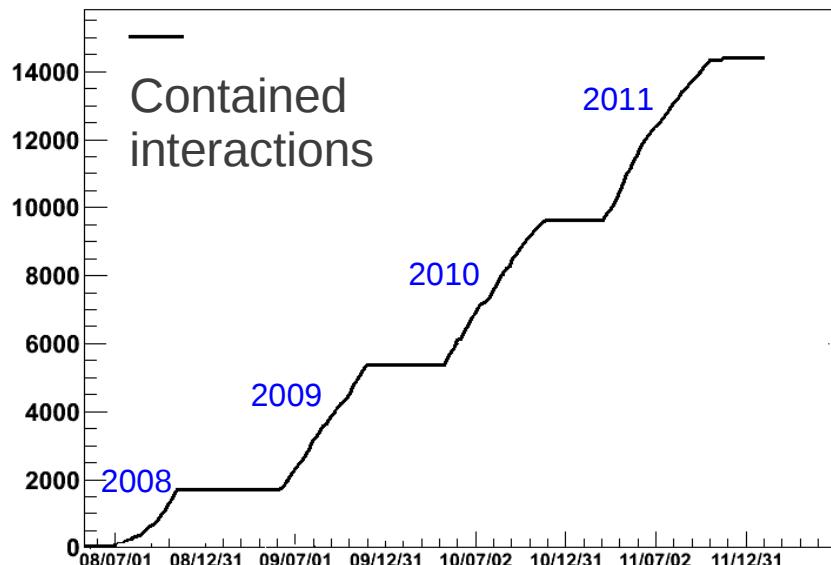

**Super Module 1****Super Module 2**

# Brick finding

**Run 2008 → 2011**

Year	Days	p.o.t. ( $10^{19}$ )	$\nu$ interactions
2008	123	1.78	1698
2009	155	3.52	3693
2010	187	4.04	4248
2011	244	4.84	4762
<b>tot</b>	<b>709</b>	<b>14.18</b>	<b>14401</b>

At the end of 2012 run (from March) we will hopefully be not to far from the design goal (22.5e19)

# CNGS beam performance

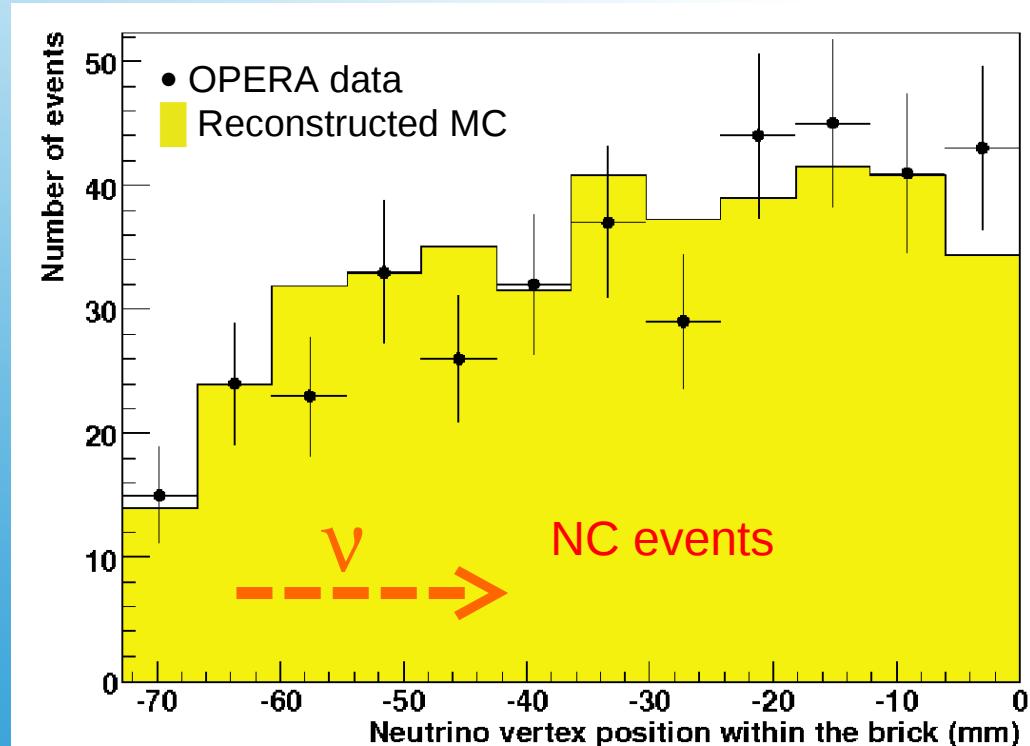

- 2008-2009 data analysis completed (arXiv:1107.2594v1) Acc. by New Journ. of Phys.
  - $4.8 \times 10^{19}$  pot, 34% of available sample, 2.6× more stat w.r.t.  $\tau$  candidate publication
  - 2738 fully analysed events (decay search). **No new  $\tau$**
- Analysis improvements

1) Search of highly ionizing tracks in hadronic interactions ( $\downarrow$  bckg for  $\tau \rightarrow h$ )

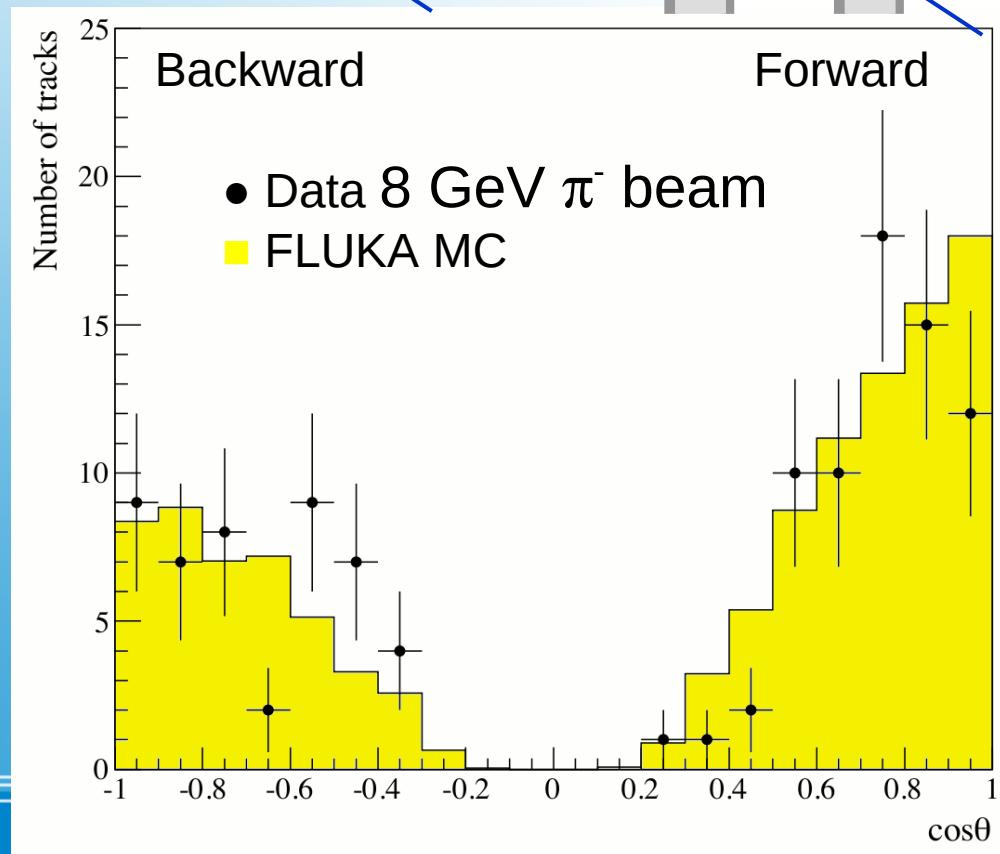

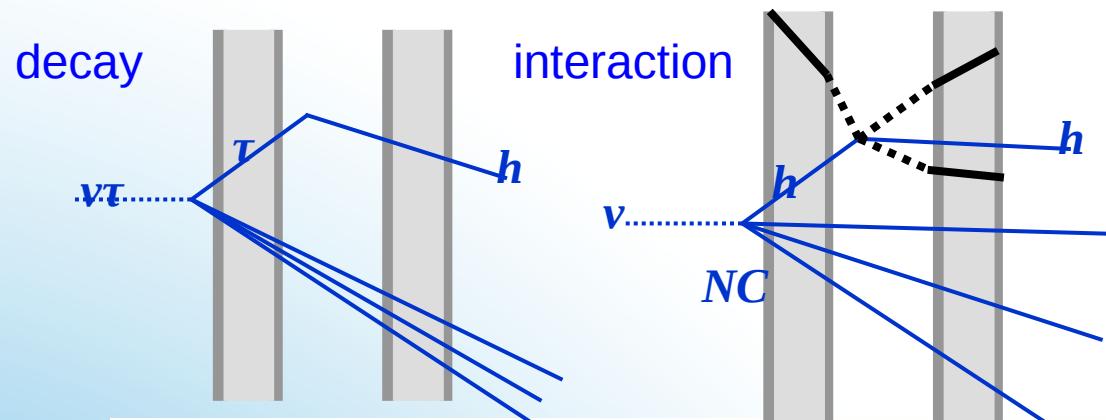

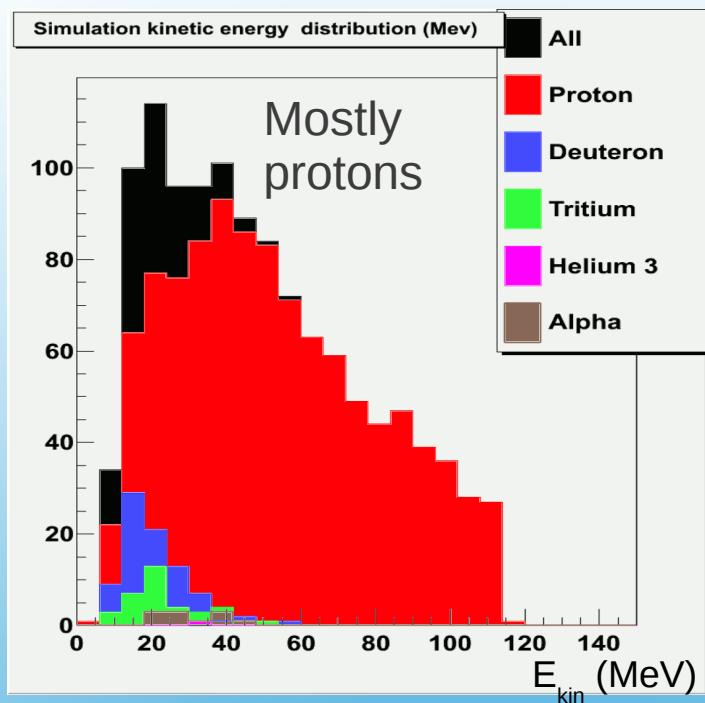

2) Follow down of vertex tracks in the emulsion  $\rightarrow$  p-range correlations  $\rightarrow$  increased  $\mu$ -ID efficiency  $\rightarrow$   $\downarrow$  charm background  
 $\downarrow$  hadronic bckg from  $\nu_\mu^{CC}$  with  $\mu$  misID

3) Implementation of state-of-the art charm cross section from CHORUS ( $\uparrow \sigma$ )

Full simulation chain with emulsion off-line reconstruction

# Statistics update and analysis improvements

Search for "black" tracks ( $\gamma\beta < 0.5$ )

Large field of view  $2.5 \times 2.1 \text{ mm}^2$

	data	FLUKA
$\geq 1$ rec. track	$(57 \pm 7) \%$	53 %
F-B asymmetry	$(0.75 \pm 0.15)$	0.71

# Highly ionizing tracks tagging

Probability for a  $\pi, K, p$  to undergo  
a single prong "kink" with

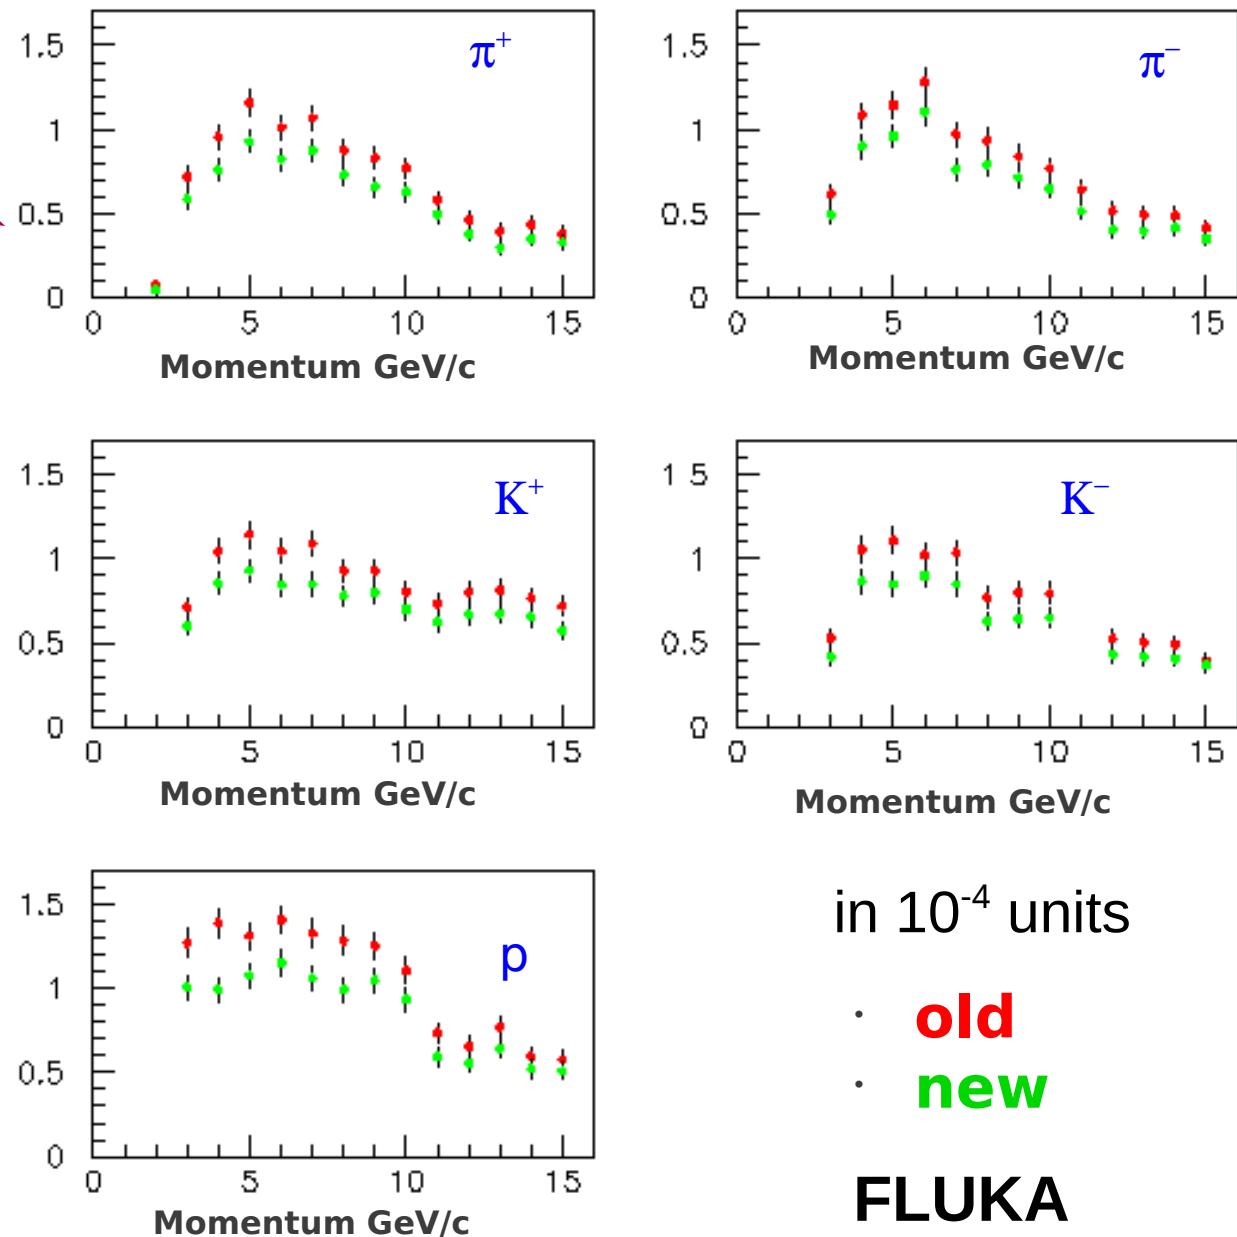

- $p > 2 \text{ GeV}/c$
- $(p_T > 0.6 \text{ GeV}/c) \text{ or } (p_T > 0.25 \text{ GeV}/c + \gamma)$

over 2 mm of lead

$$1.53 \times 10^{-4} / \text{NC}$$

-20% w.r.t. old  
estimation

Improvements: larger angular  
acceptance and lower  
momentum threshold for  
additional protons and fragments

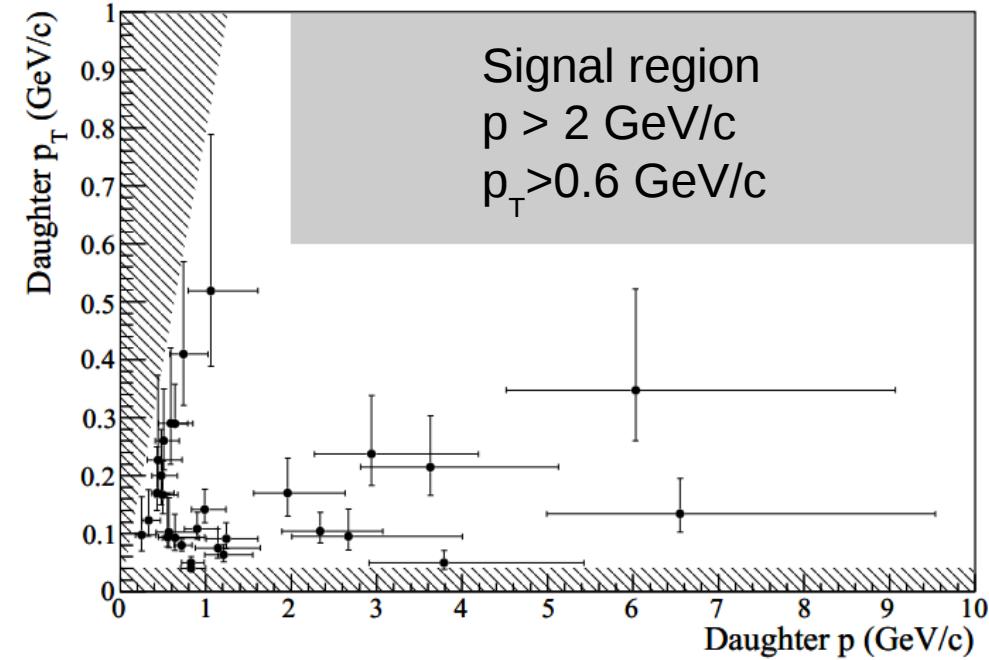

in  $10^{-4}$  units

- **old**
- **new**

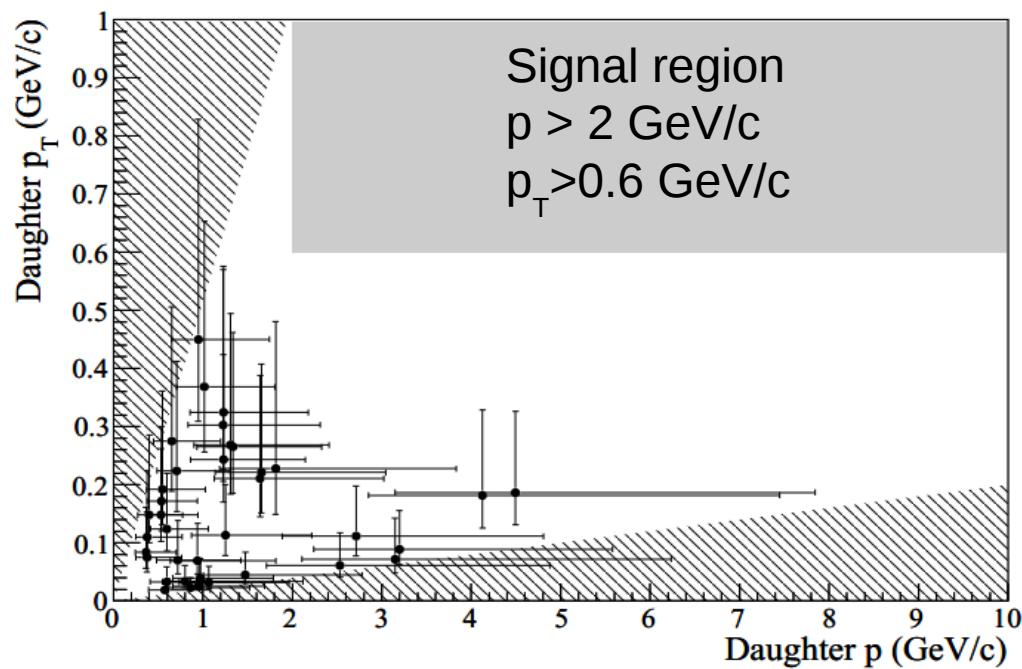

**FLUKA**

# Hadronic background MC

## OPERA neutrino interactions

## 4 GeV $\pi$ test beam

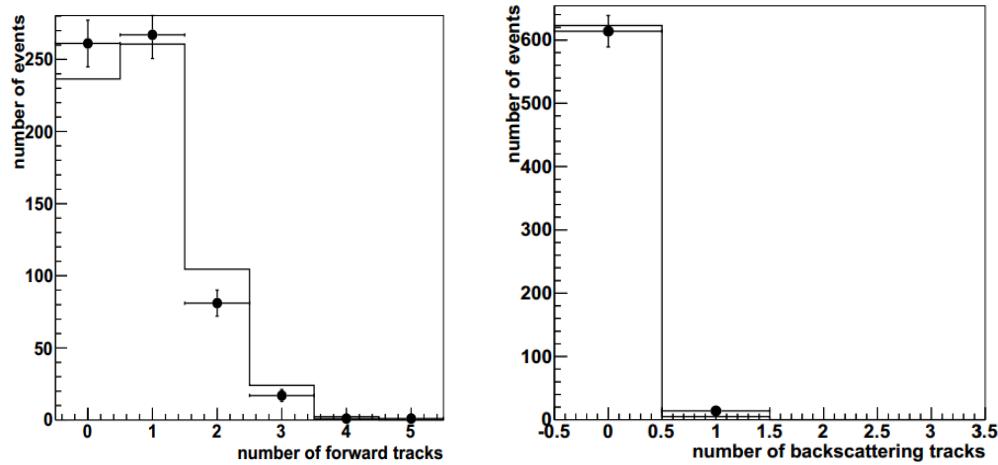

14 m, equivalent to 2300 NC events

No events in signal region

$p_T > 200 \text{ MeV}/c$ :

observed 10  
expected 10.8

# Data driven hadron background constraints

	CHORUS [%] arXiv:1107.0613 [hep-ex]	@ OPERA [%]	Former value

Daughter $P_T$ when $\gamma$ -ray at the decay vertex ( $\text{GeV}/c$ )	$> 0.3$	$0.47^{+0.24}_{-0.12}$
Decay length ( $\mu\text{m}$ )	$< 2$ lead plates	$1335 \pm 35$

## Run 2008 → 2011

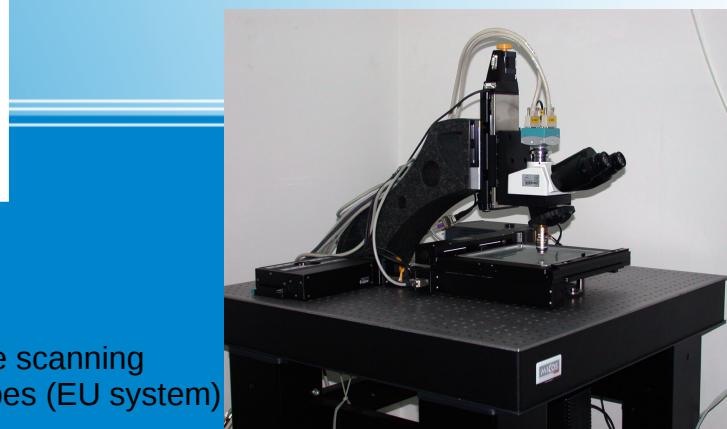

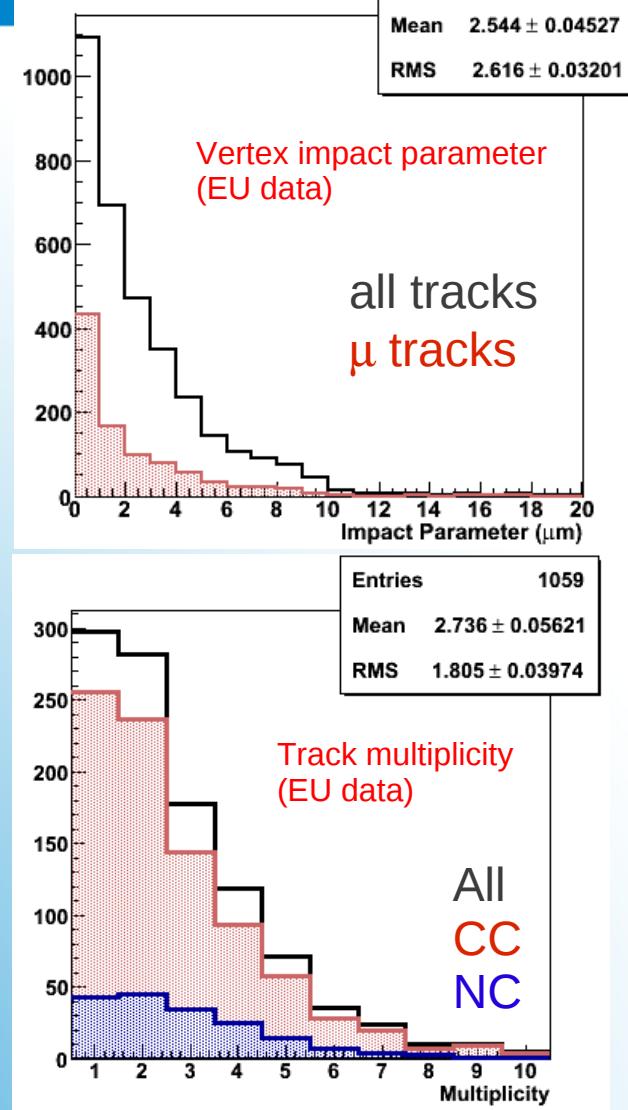

Steady progress: 4268 v vertices in the emulsions 88% with full decay search done, 55 charm, 24  $\nu_e$  events

2010/2011 data, new strategy being followed: prioritize scanning of  $\tau$  enriched sample (NC-like or  $p_\mu < 15$  GeV/c)

Relevant p.o.t. for  $\tau$  search will scale faster with time wrt the past (inclusive scanning). Detailed report at summer conferences.

# Scanning progress

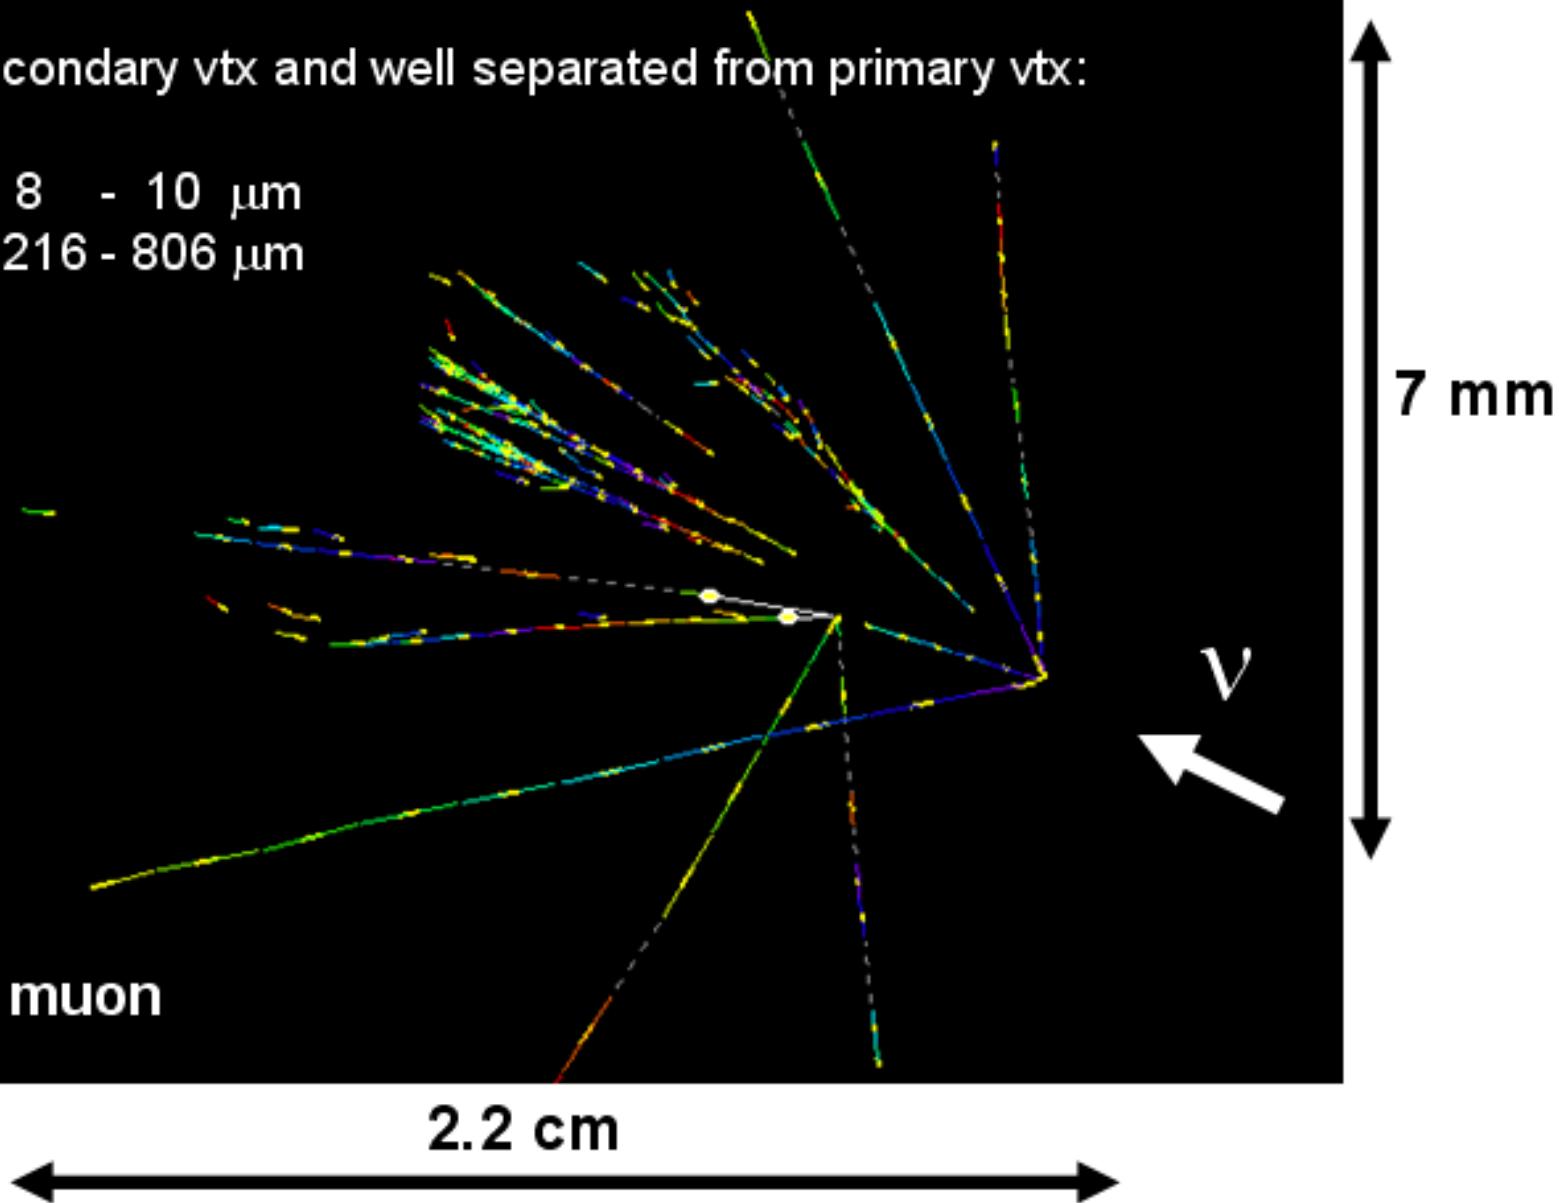

One of the scanning microscopes (EU system)

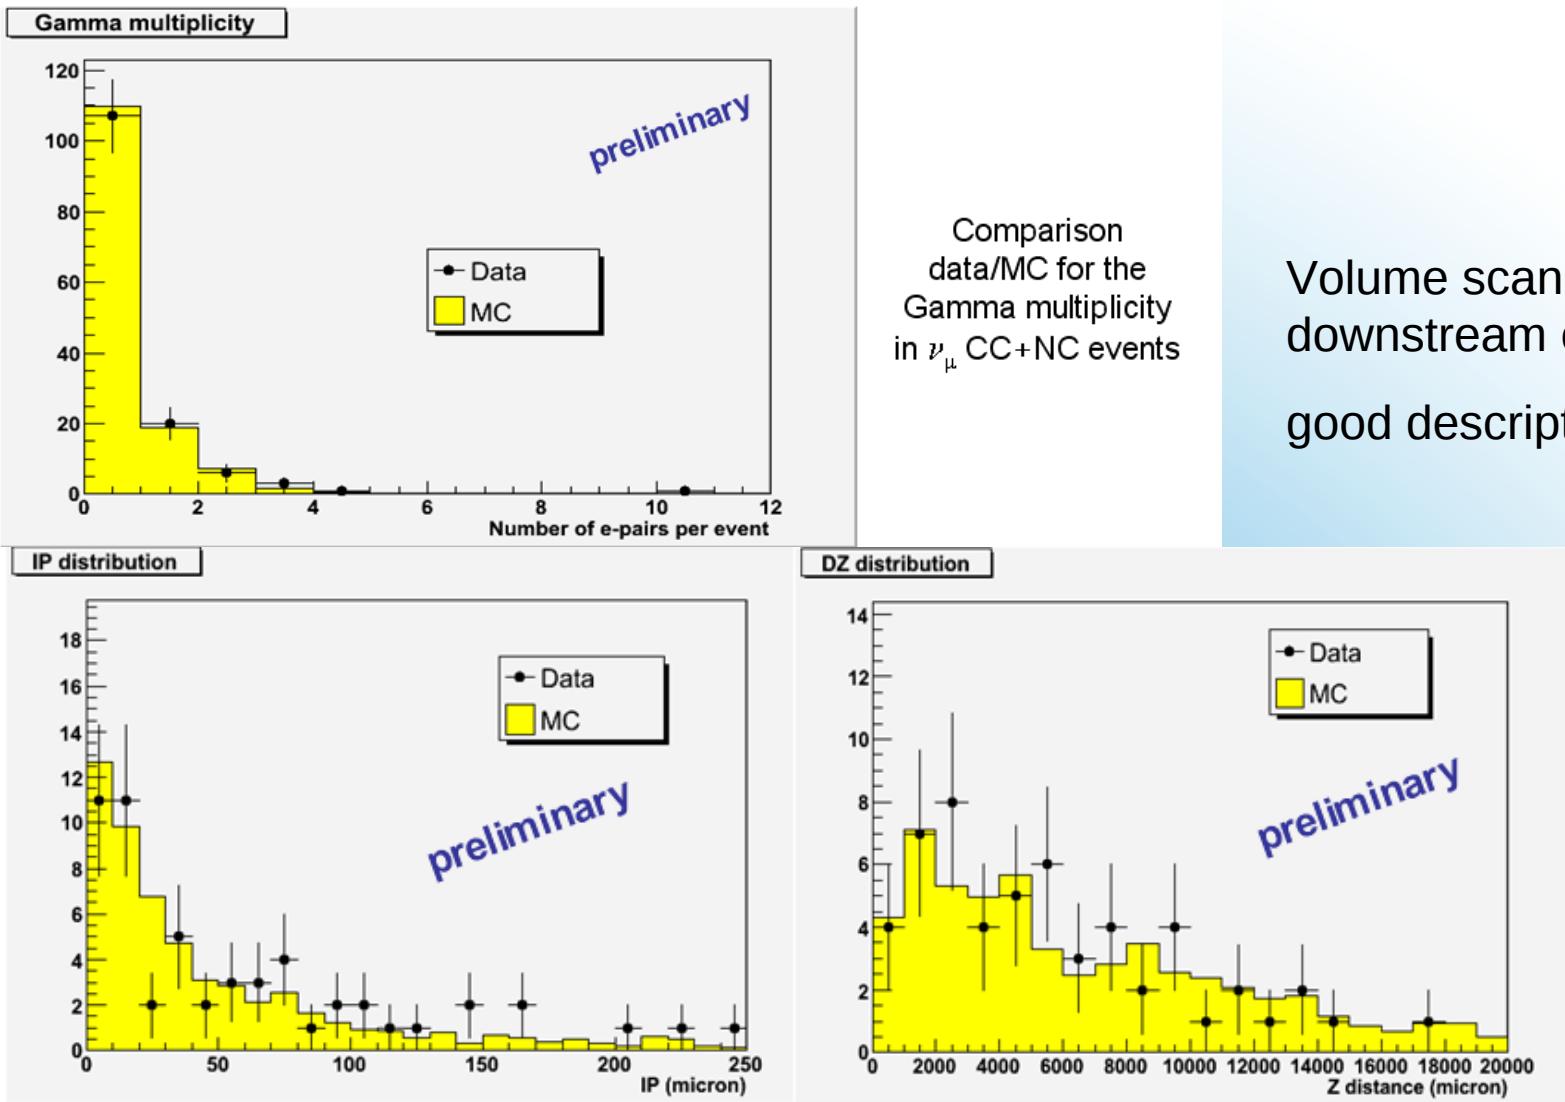

6  $\gamma$  reconstructed around the vertex

2  $\gamma$  attached to secondary vtx and well separated from primary vtx:

- IP at 2ry vtx: 8 - 10  $\mu\text{m}$
- IP at 1ry vtx: 1216 - 806  $\mu\text{m}$

$\gamma$  reconstruction

# $\gamma$ conversions: data/MC

Currently 24  $\nu_e$  events as the by-product of  $\nu_\tau$  search

- A dedicated strategy using **shower signature in the CS doublet** is being pursued to increase efficiency.

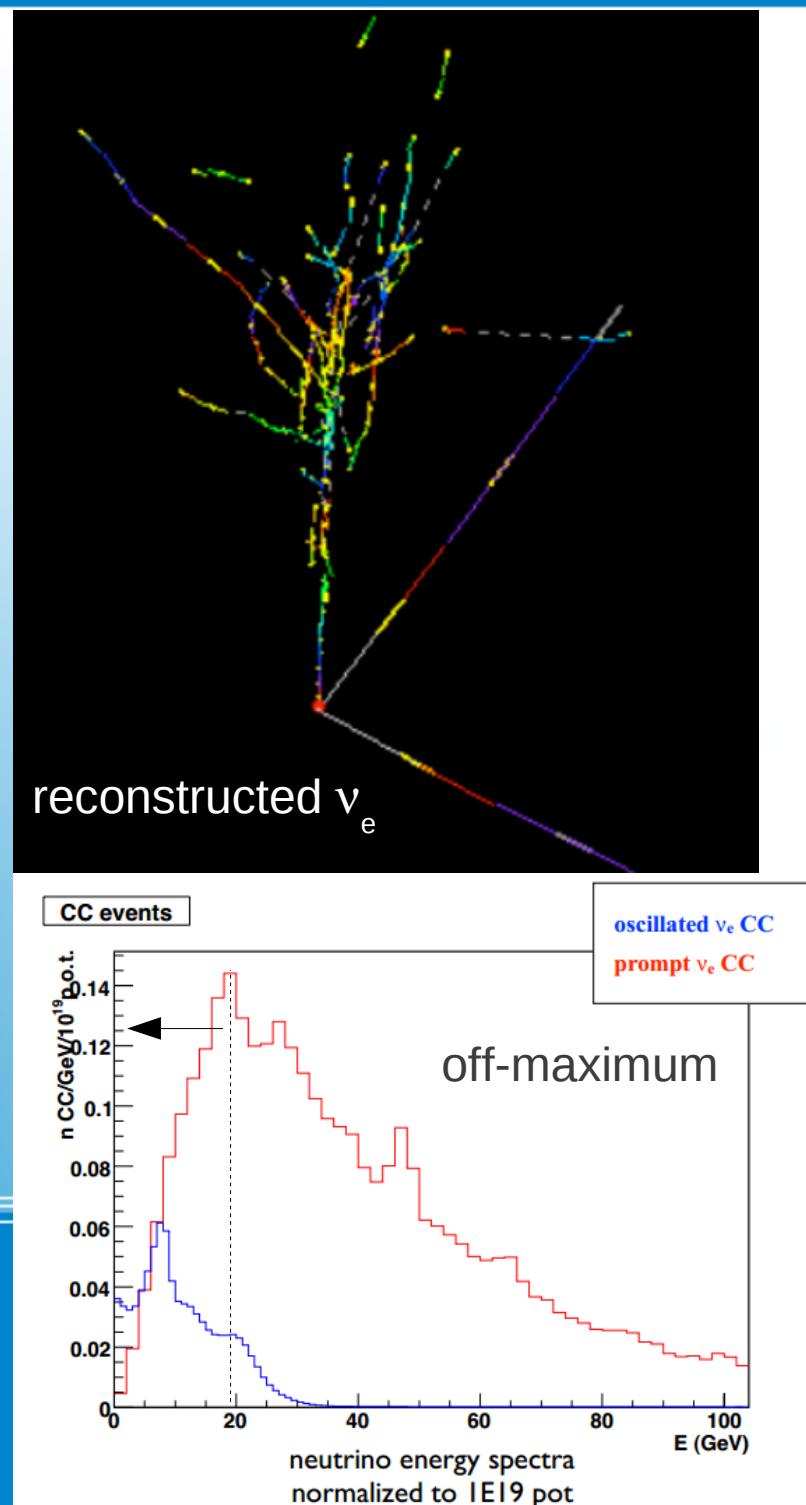

In progress:

- **efficiency** evaluation with complete simulation framework well advanced
- **energy reconstruction** tuning
- **backgrounds**: prompt  $\nu_e$  and  $\gamma$  conversions

$E < 20$ GeV	2008-2009 preliminary estimation	$22.5 \times 10^{19}$
$\nu_e$ (prompt)	2.8	13.1
$\tau \rightarrow e + NC\pi^0$	1.6	7.5
$\sin^2 2\theta_{13} = 0.11$	1.2	5.6

- Plans for publication of 2008-09 sample in 2012

# $\nu_e$ sample

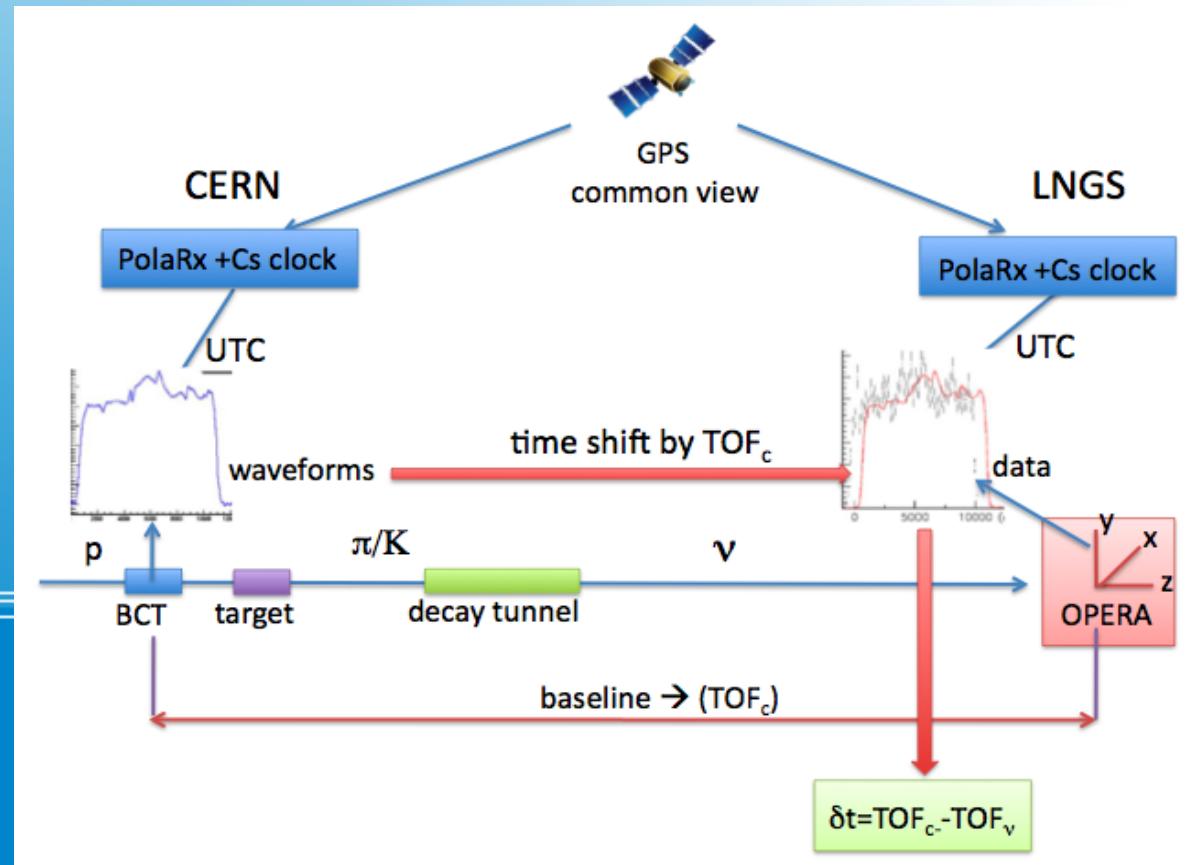

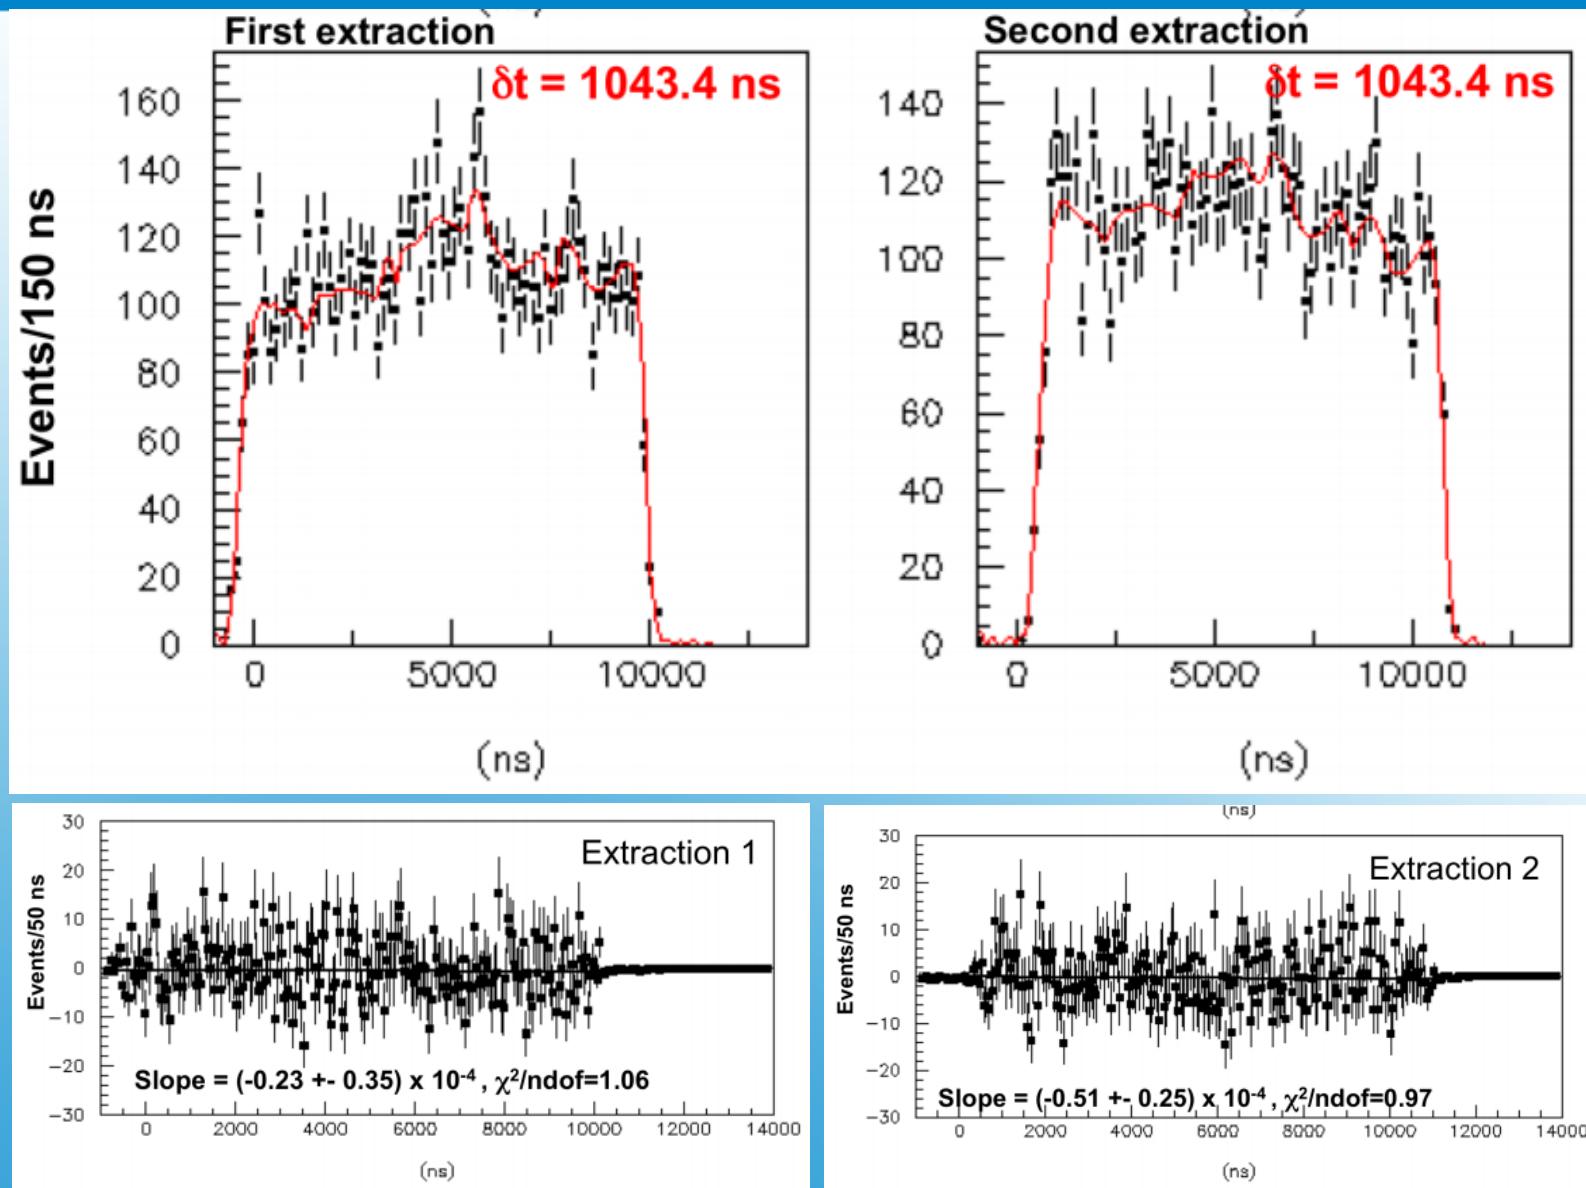

- Basic ingredients\*: \* will omit plenty of details and cross checks arXiv:1109.4897

- CNGS-OPERA synchronization at  $\sim 1\text{ns}$  (**GPS common view mode**)
- Calibrations of the timing chains at CERN and OPERA
- $\nu$  time distribution at CERN through **proton waveforms with BCT**
- High  $\nu$  energy - **high statistics** ( $\sim 15\text{k events}$ )
- **Geodesy**: 20 cm accuracy over 730 km

**$\nu$ -TOF**

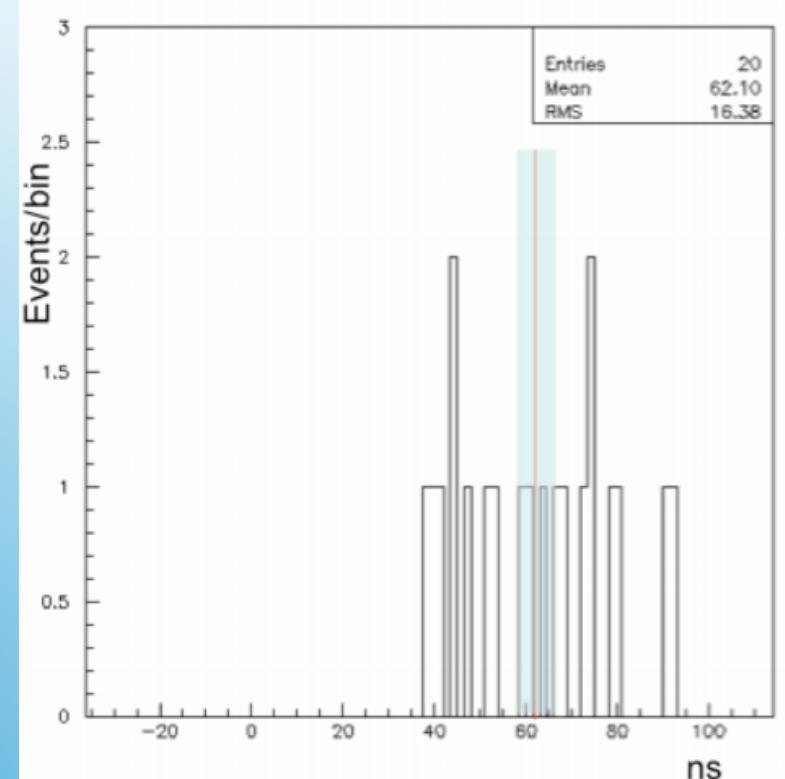

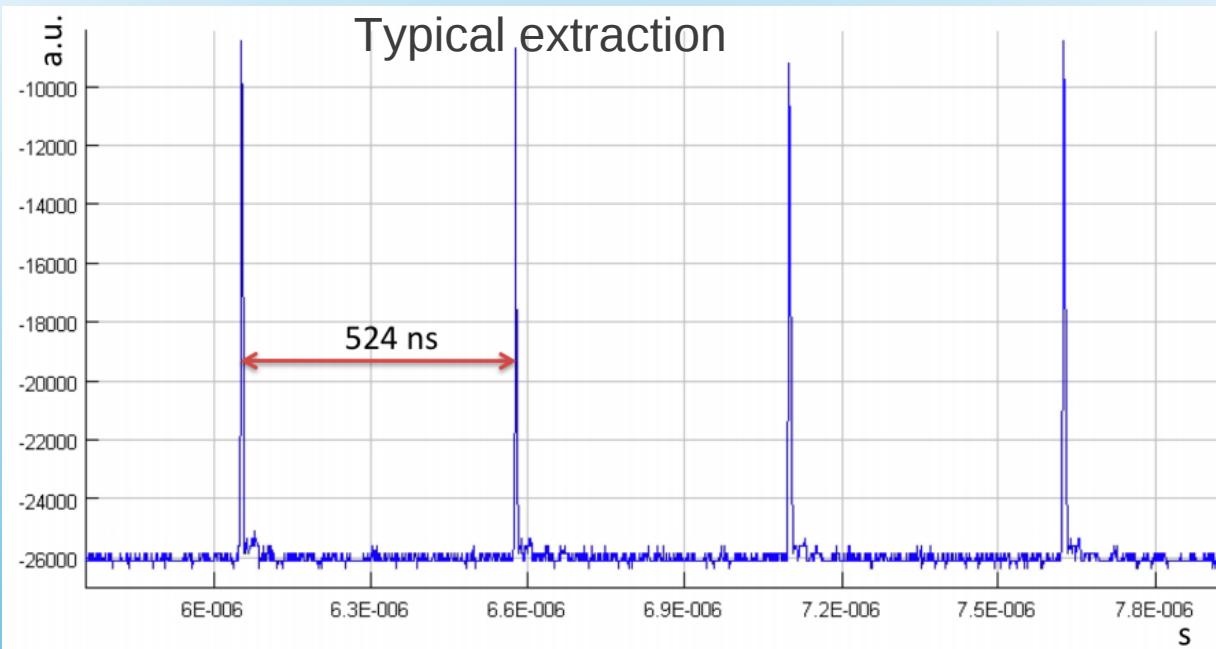

$57.8 \pm 7.8 \text{ (stat.) ns}$  anomaly after un-blinding for measured delay chains

## Analysis with the standard beam

November 2011, bunched beam:

The robustness of statistical treatment is confirmed and anomaly persists ( $62.1 \pm 3.7$ ) ns

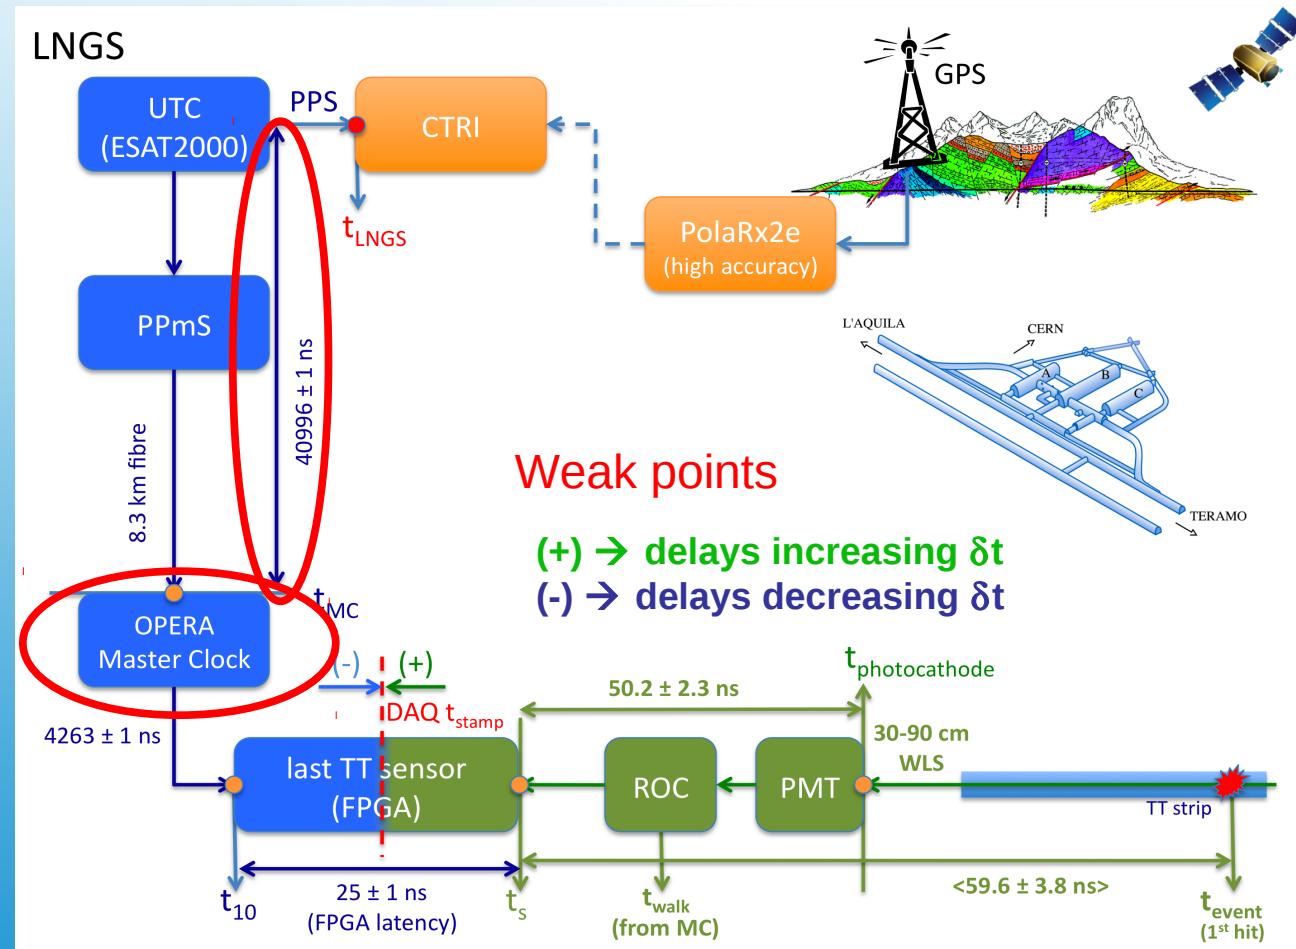

October 22 to November 6, 2011

# Analysis with a "bunched-beam"

## Official statement (23/2/2012)

"The OPERA Collaboration, by continuing its campaign of verifications on the neutrino velocity measurement, has identified two issues that could significantly affect the reported result. The first one is linked to the oscillator used to produce the events time-stamps in between the GPS synchronizations. The second point is related to the connection of the optical fiber bringing the external GPS signal to the OPERA master Clock.

These two issues can modify the neutrino time of flight in opposite directions. While continuing our investigations, in order to unambiguously quantify the effect on the observed result, the Collaboration is looking forward to performing a new measurement of the neutrino velocity as soon as a new bunched beam will be available in 2012. An extensive report on the above mentioned verifications and results will be shortly made available to the scientific committees and agencies."

## Recent findings

## Oscillation:

- $1 \nu_\tau$  candidate, with an expectation of 1.65 signal and  $0.05 \pm 0.01$  background events.
- The analyzed sample (2008-2009) corresponds to  $\sim 21\%$  of the overall nominal statistics of which 63 % has been collected so far ( $14.1\text{e}19$  pot).
- 2012 run will hopefully bring us close to nominal statistics ( $22.5\text{e}19$ ,  $7.6 \tau$  expected)
- Improvement in the analysis and (data driven) background control achieved and being pursued further.
- Constant progress in scanned events statistics: a really demanding task!
- Update at summer conferences foreseen with signal expectation significantly  $> 1$ .
- $\nu_e$  appearance results in 2012 on 2008/2009 sample.

## $\nu$ -TOF:

- Two issues that could significantly affect the reported TOF anomaly have been identified
- A new bunched beam run in 2012 requested to provide a clarified picture.

# Summary

# Back-up slides

Decay channel	Number of background events for:							
	$22.5 \times 10^{19}$ p.o.t.				Analysed sample			
	Charm	Hadr.	Muon	Total	Charm	Hadr.	Muon	Total
$t \rightarrow \mu$	0.025	0.00	0.07	$0.09 \pm 0.04$	0.00	0.00	0.02	$0.02 \pm 0.01$
$t \rightarrow e$	0.22			$0.22 \pm 0.05$	0.05			$0.05 \pm 0.01$
$t \rightarrow h$	0.14	0.11		$0.24 \pm 0.06$	0.03	0.02		$0.05 \pm 0.01$
$t \rightarrow 3h$	0.18			$0.18 \pm 0.04$	0.04			$0.04 \pm 0.01$
Total	0.55	0.11	0.07	$0.73 \pm 0.15$	0.12	0.02	0.02	$0.16 \pm 0.03$

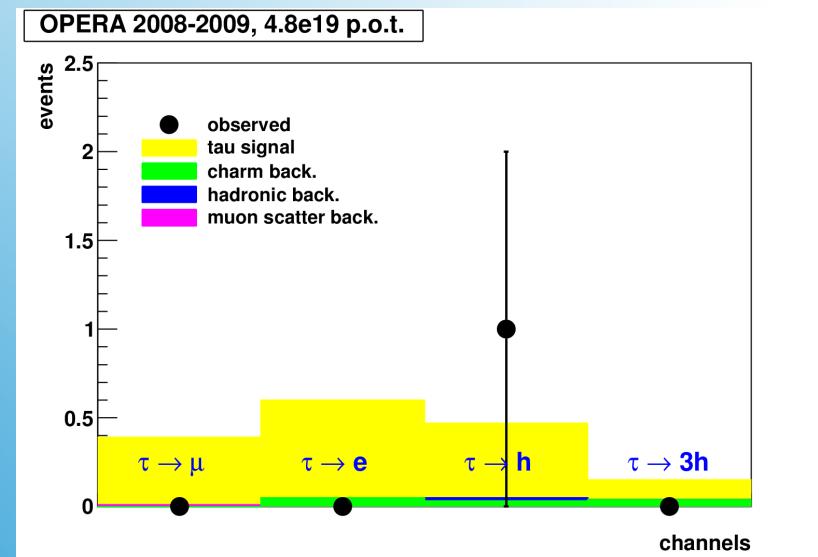

$\tau \rightarrow \mu$  is very clean

Expected background in  $t \rightarrow h$ :  $0.05 \pm 0.01$

Probability of a background fluctuation up to at least one event is 5%

Total background:  $0.16 \pm 0.03$

Probability background fluctuation 15%

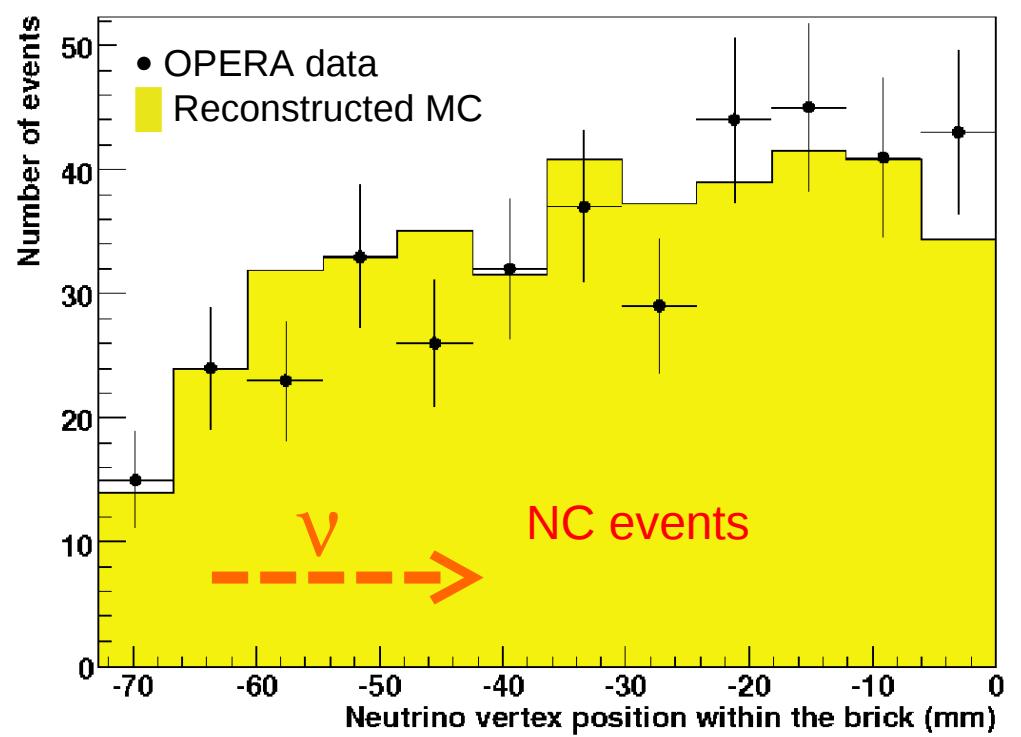

# Summary of background

	0 mu	1 mu	All
Triggered (CNGS on-time)			<b>31576</b>
predicted by the target tracker	1503	3752	5255
located in dead material	54	245	299
located in the ECC	519	2280	2799
decay search performed	494	2244	<b>2738</b>

85% are events induced by neutrino interaction outside OPERA target

→ 92% of the expected sample that could be decay searched ( $2978 \pm 75$ )

## Location efficiency:

- CC: 74 %
- NC: 48 %

Full simulation chain including newly developed off-line emulsion reconstruction software

# 2008-2009 sample

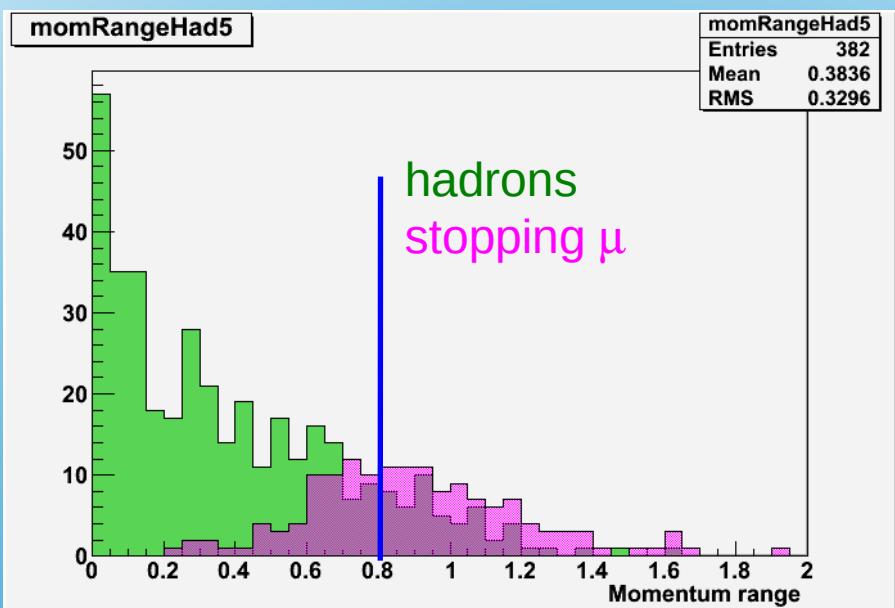

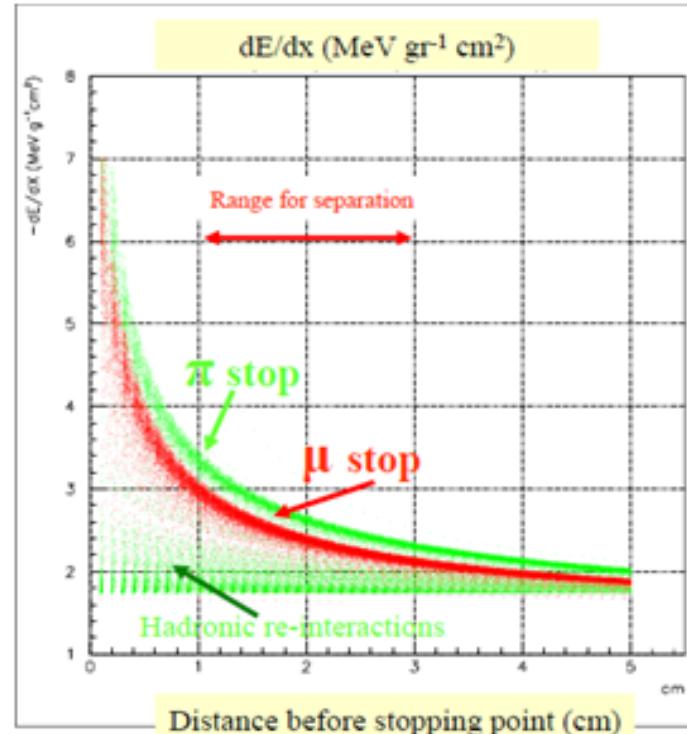

## Tracks classification:

- visible interaction in the brick
- $dE/dx$  at end point (  $\pi/\mu$  separation )
- Momentum/range correlation

Discriminating variable

$$D = \frac{L}{R_{\text{lead}}(p)} \frac{\rho_{\text{lead}}}{\rho_{\text{average}}}$$

$L$  = track length  
 $R_{\text{lead}}$  =  $\mu$  range in  
 $p$  = momentum  
measured  
in the emulsion

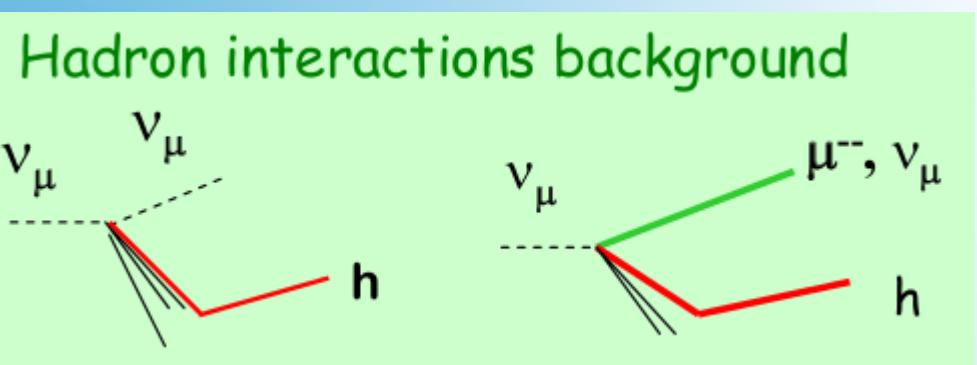

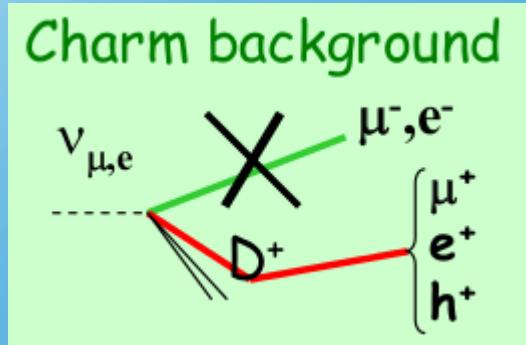

- 34% reduction of  $\mu$  mis-ID in charm events (3.28%)
- 2 orders of magnitude reduction for the hadronic background to  $\tau \rightarrow \mu$  due to  $\mu$  mismatch in CC and NC events

# Track Follow Down

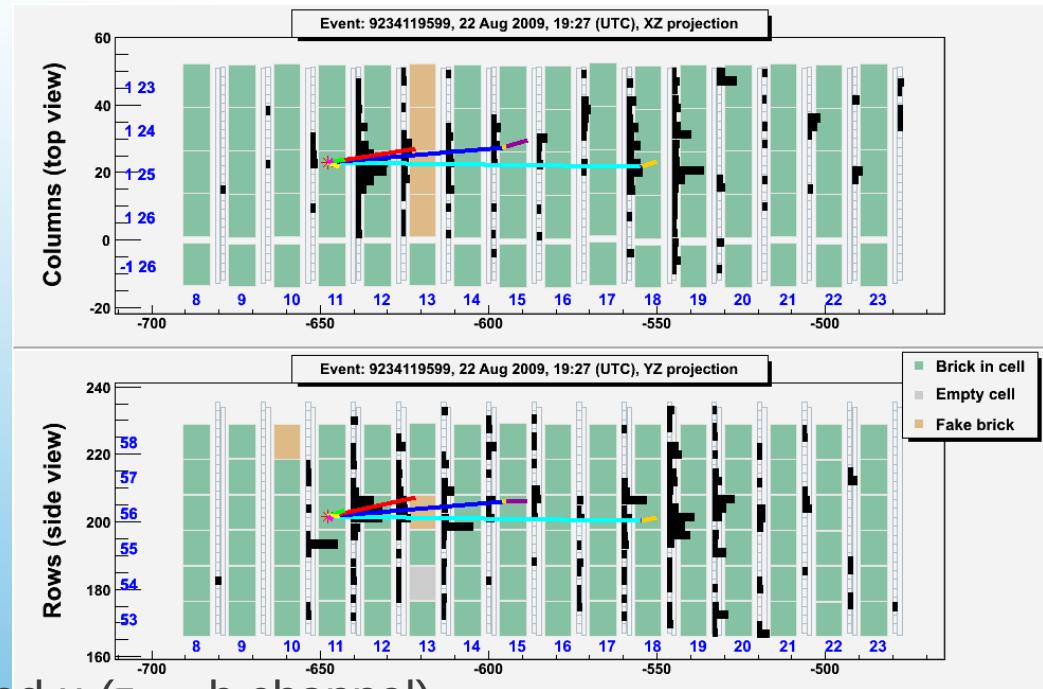

- For the first  $\nu_\tau$  candidate we followed down all the tracks to search for possible muon not identified by the electronic detectors

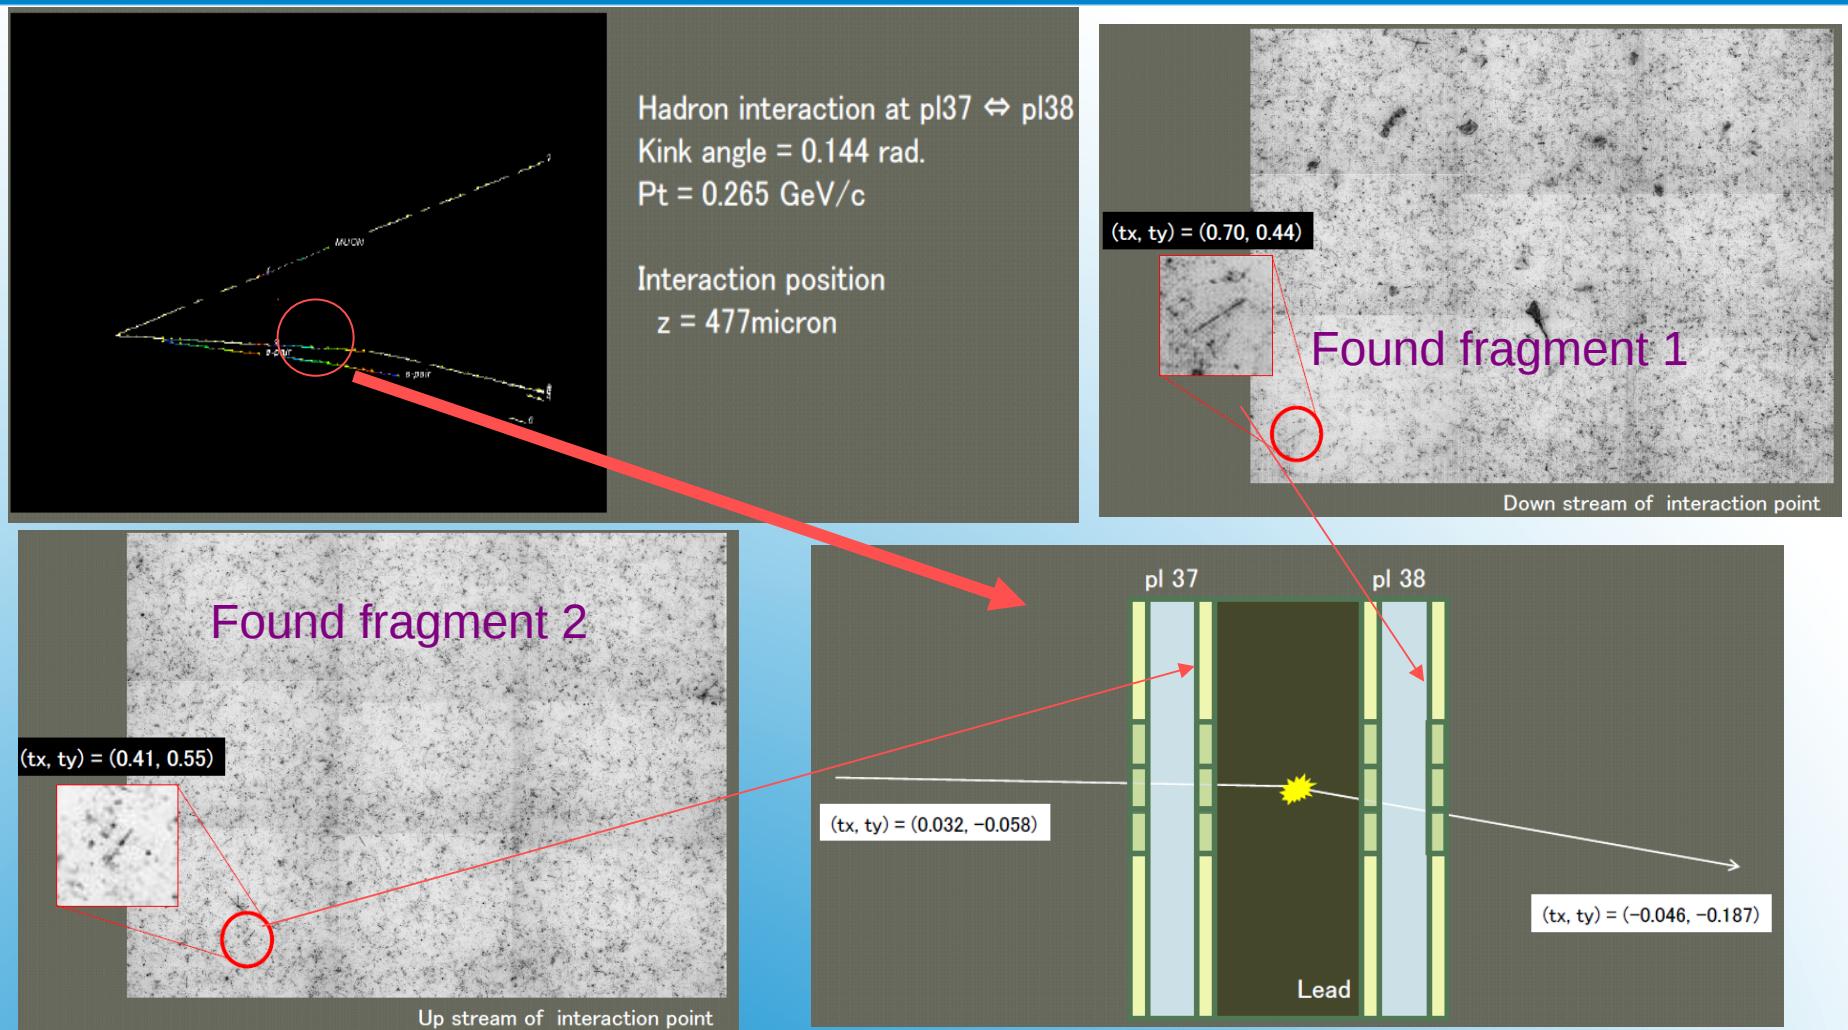

We can suppress backgrounds due to

- Charm
- Hadron interactions in  $\nu\mu$  CC with misidentified  $\mu$  ( $\tau \rightarrow h$  channel)
- Hadron interactions in  $\nu\mu$  CC and NC ( $\tau \rightarrow \mu$  channel)

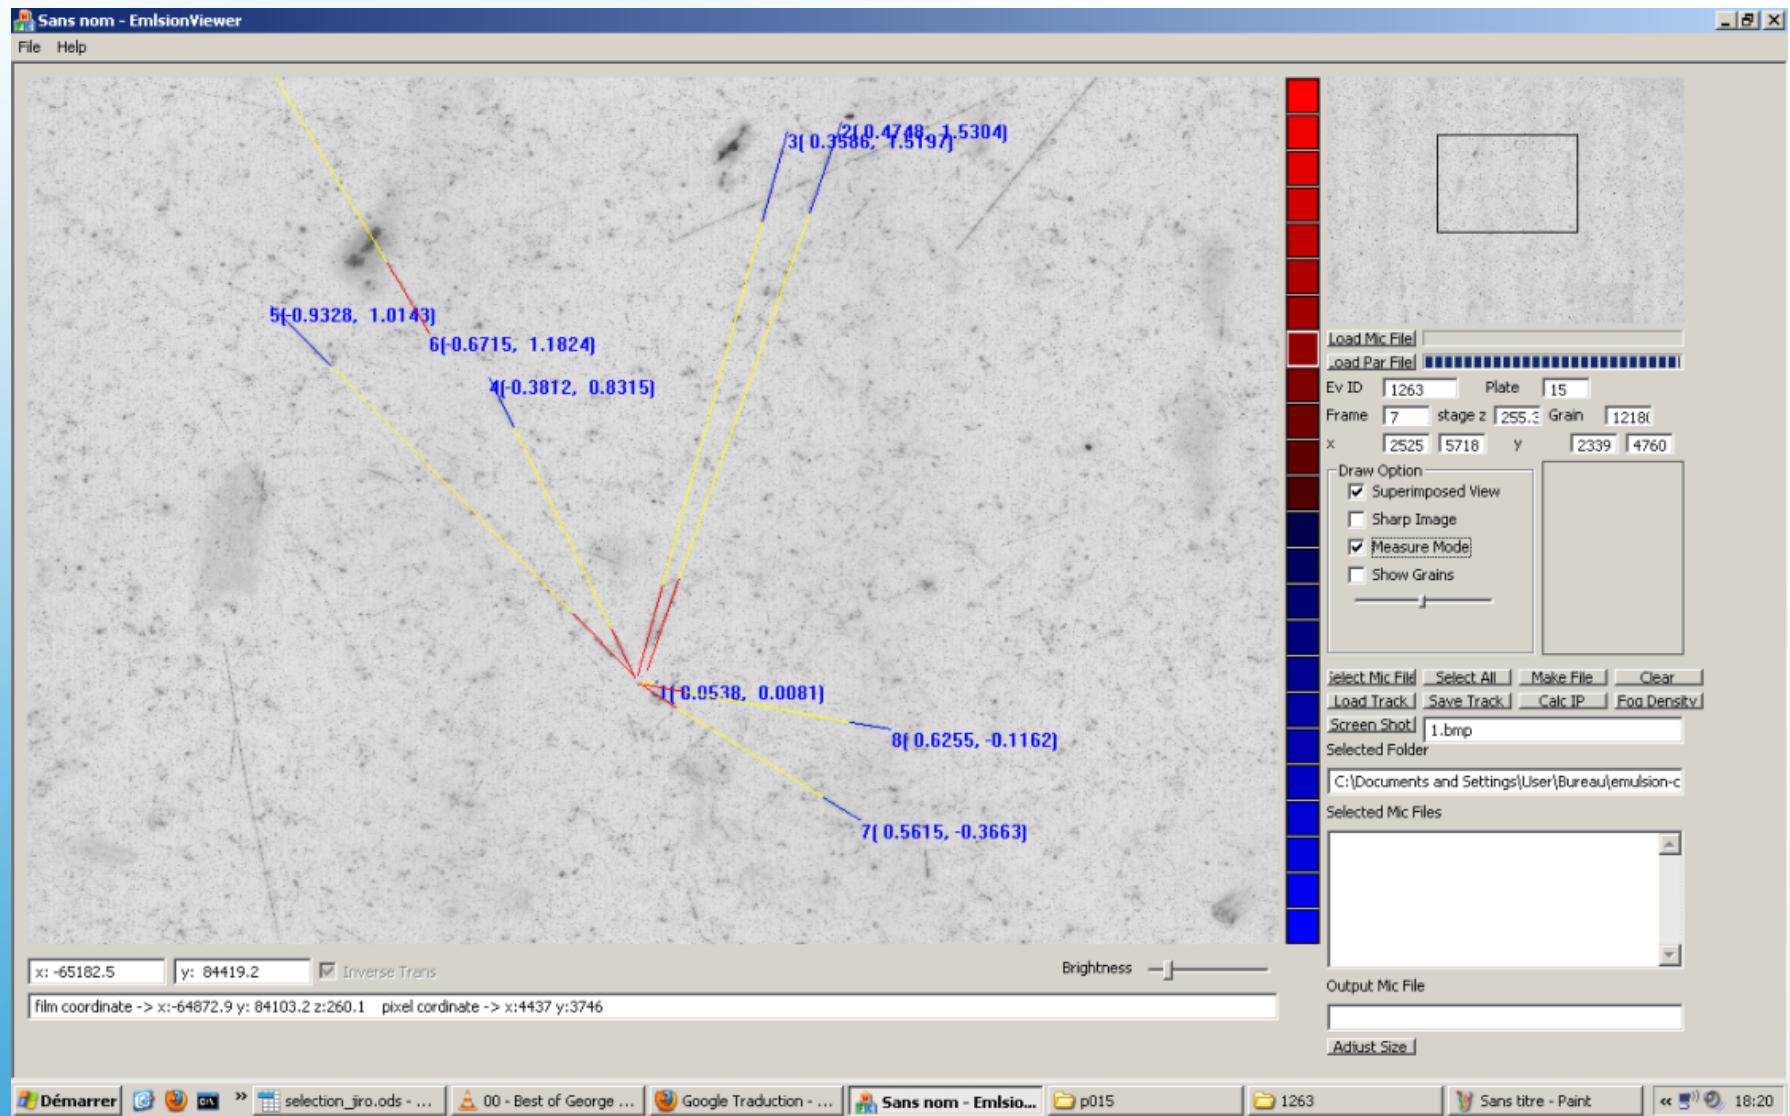

# Track Follow Down

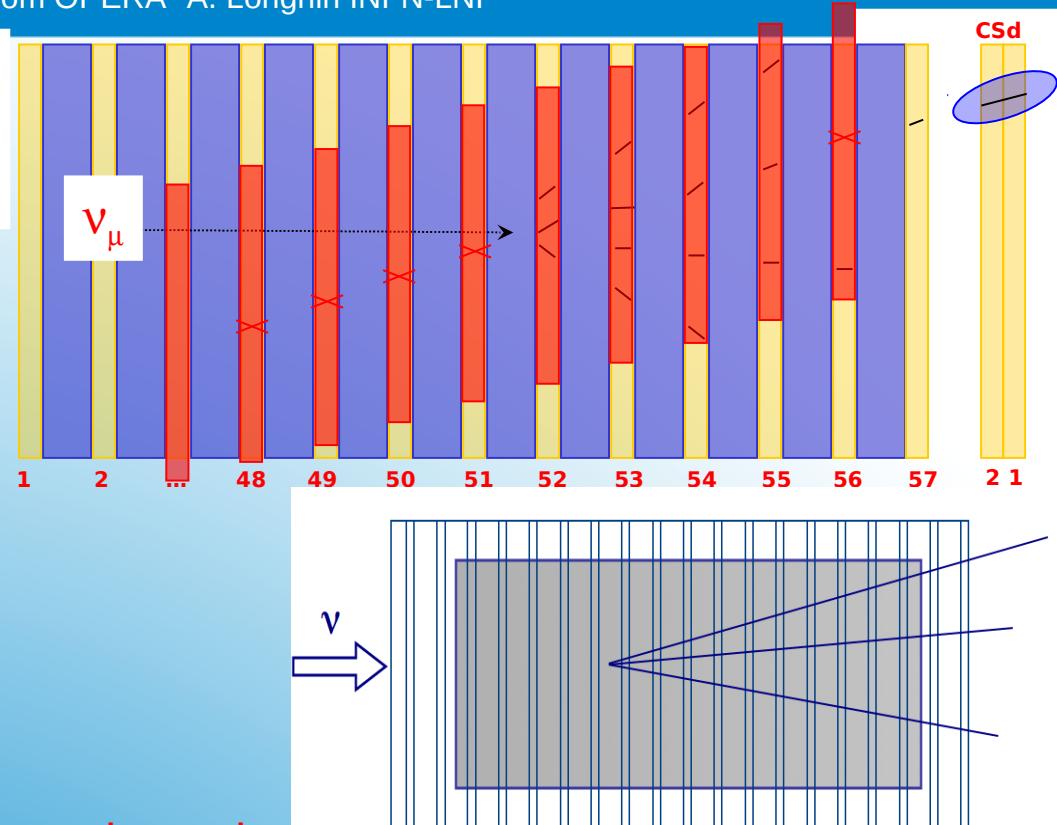

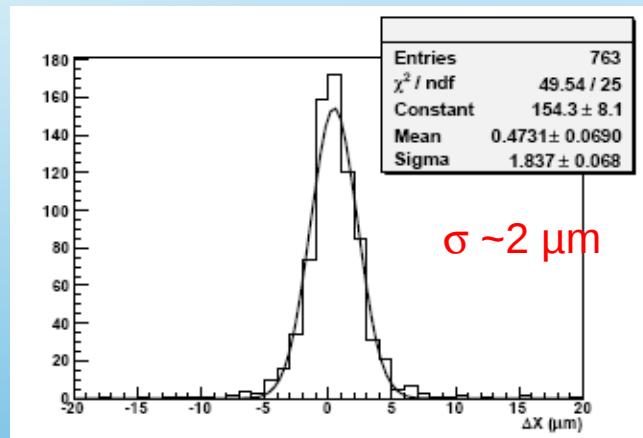

Intra-nuclear interactions and nuclear evaporation  $\rightarrow$  p and nuclear fragments emission  
High-efficiency tagging to reduce the hadronic background

# Tagging of highly ionizing particles in hadron interactions

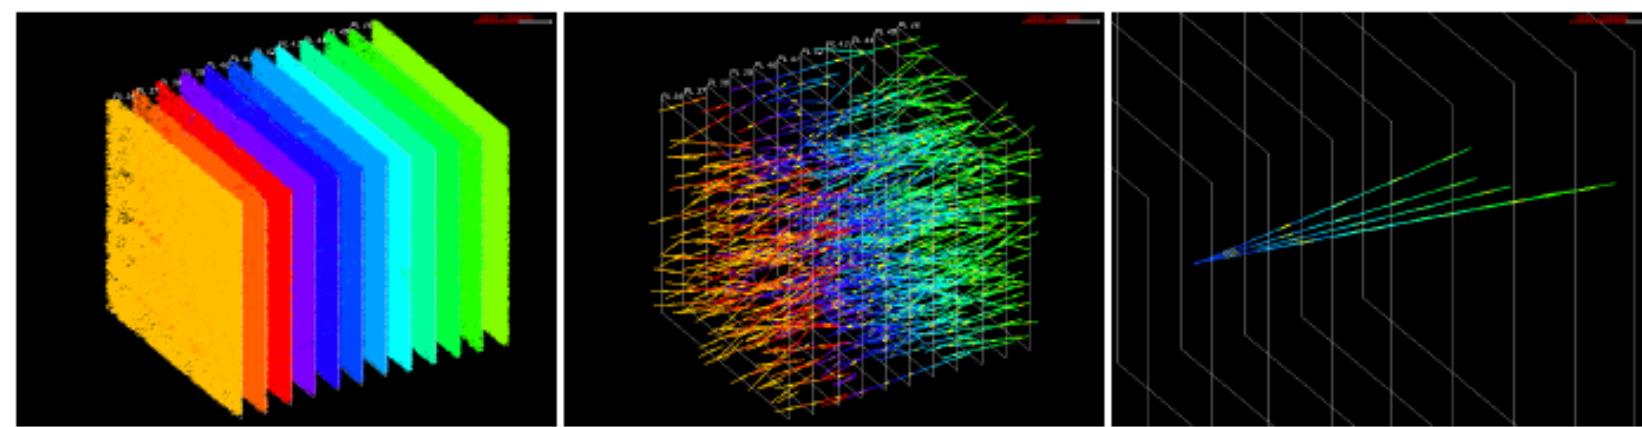

## Track follow-up film by film:

- alignment using cosmic ray tracks
- definition of the stopping point

Volume scanning ( $\sim 2 \text{ cm}^3$ ) around the stopping point

# Vertex finding

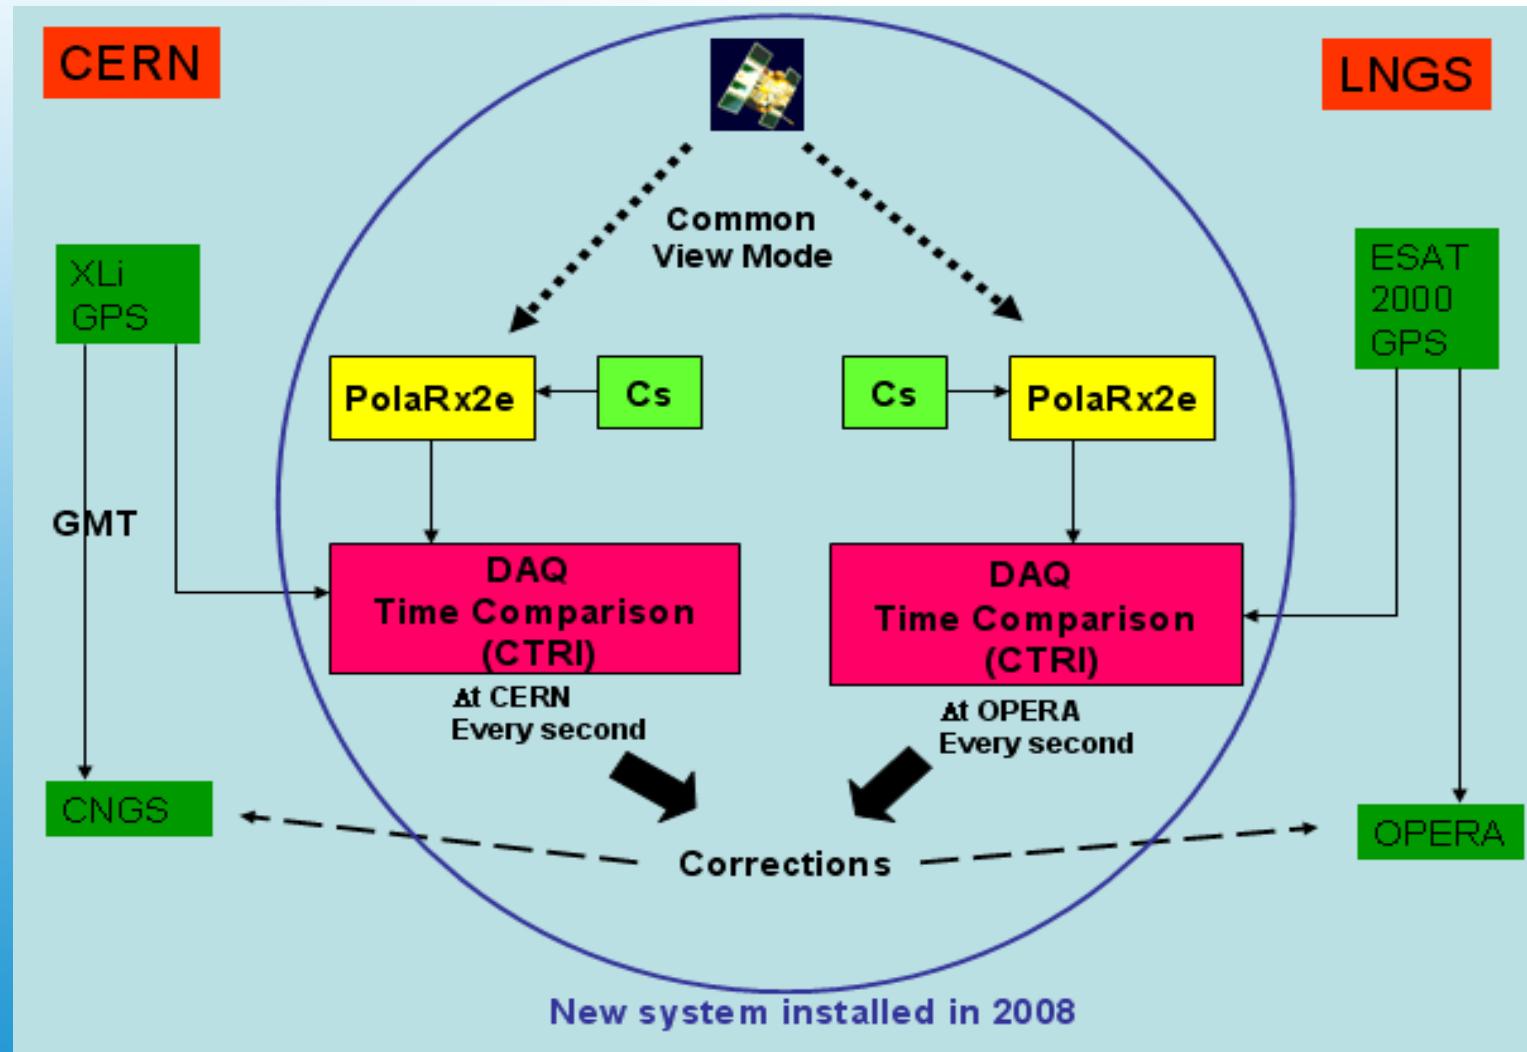

Standard GPS receivers have ~100 ns accuracy:

- XLi (CERN)
- ESAT 2000 (LNGS)

2008: installation of a twin high accuracy system calibrated by METAS (Swiss metrology institute)

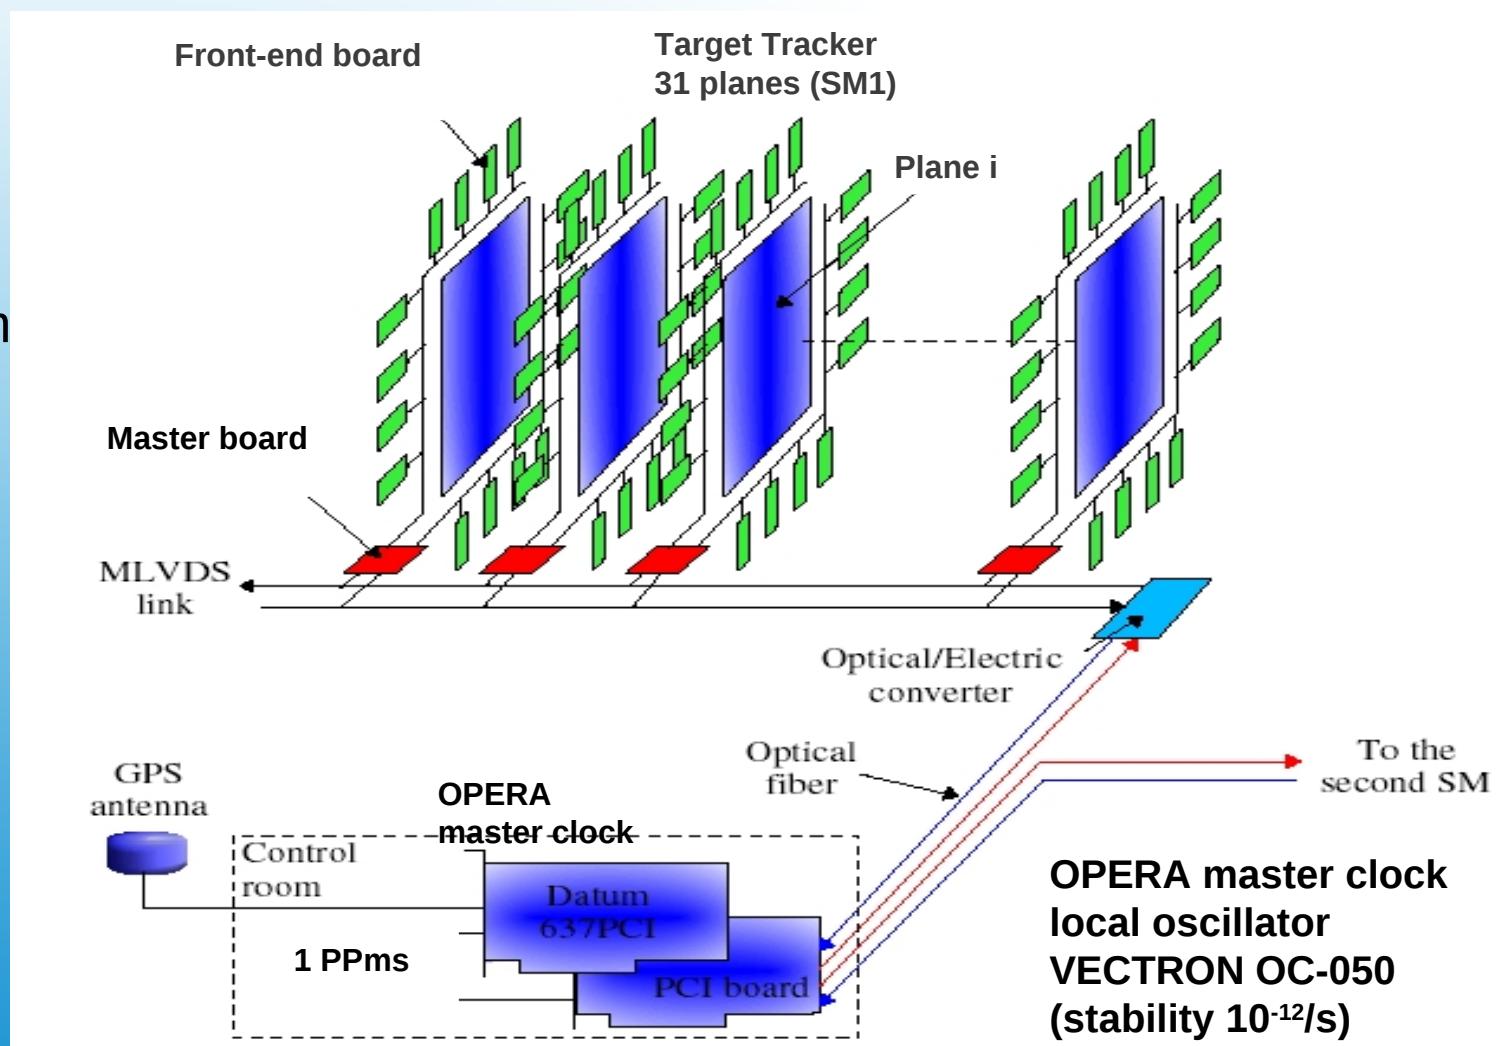

- PolaRx2e GPS receiver
- Cs-clock

at CERN and LNGS

# CNGS OPERA synchronization

- 1200 asynchronous **FE-nodes**
- Gigabit ethernet network
- “trigger-less” system
- for each FE node **mezzanine card**: CPU (embedded Linux), memory, FPGA, clock receiver
- 10 ns UTC event time stamp granularity

# OPERA read-out system and clock distribution

LNFS

## Rome La Sapienza Geodesy group

Dedicated measurements:  
July-Sept. 2010

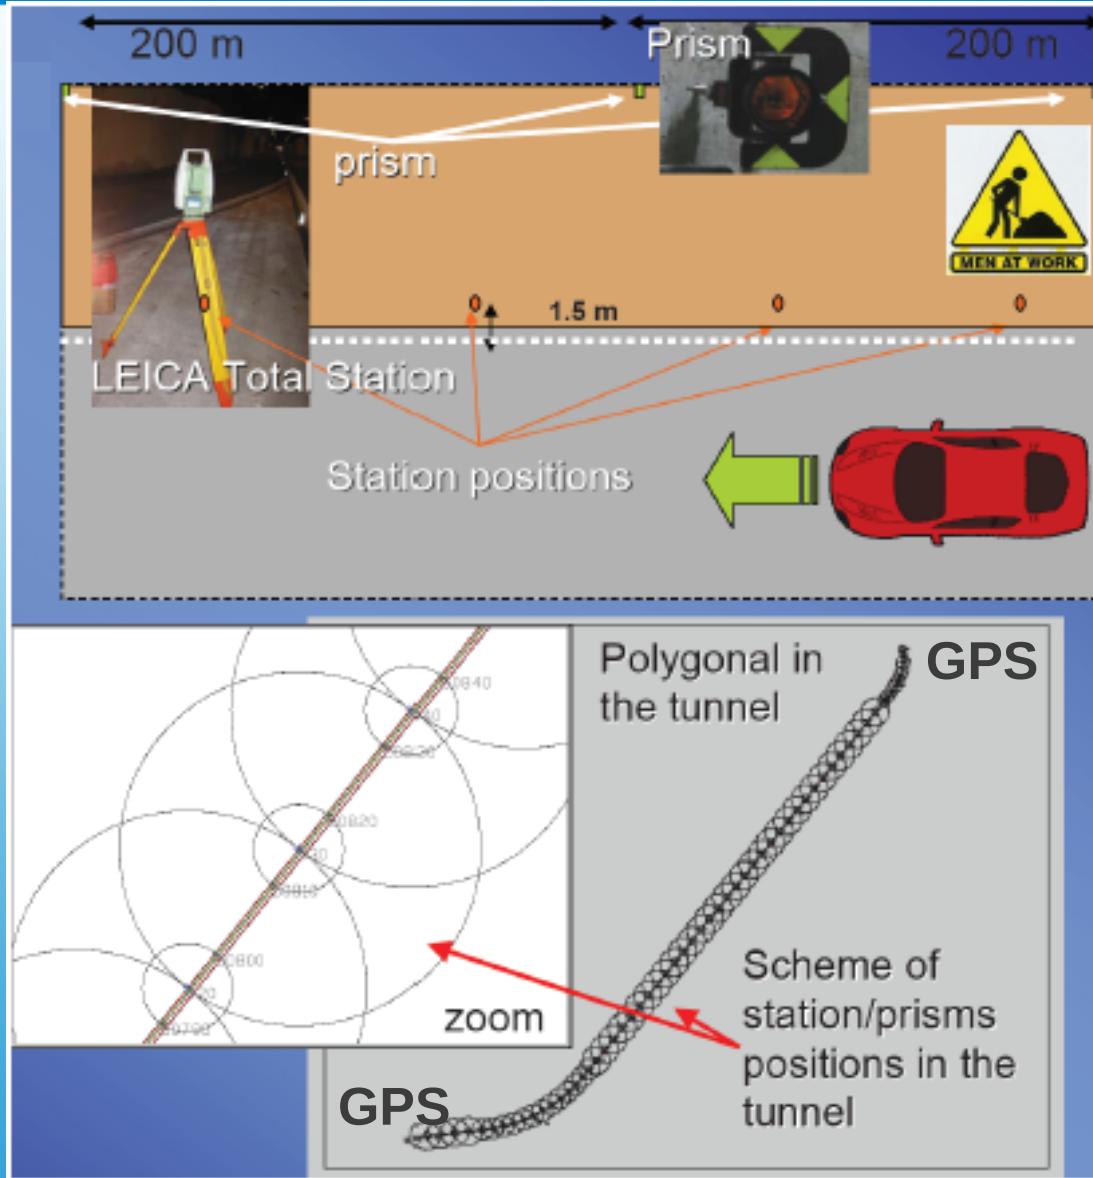

2 new GPS benchmarks on each side  
of the 10 km highway tunnel

GPS measurements ported  
underground to OPERA

## CERN survey group

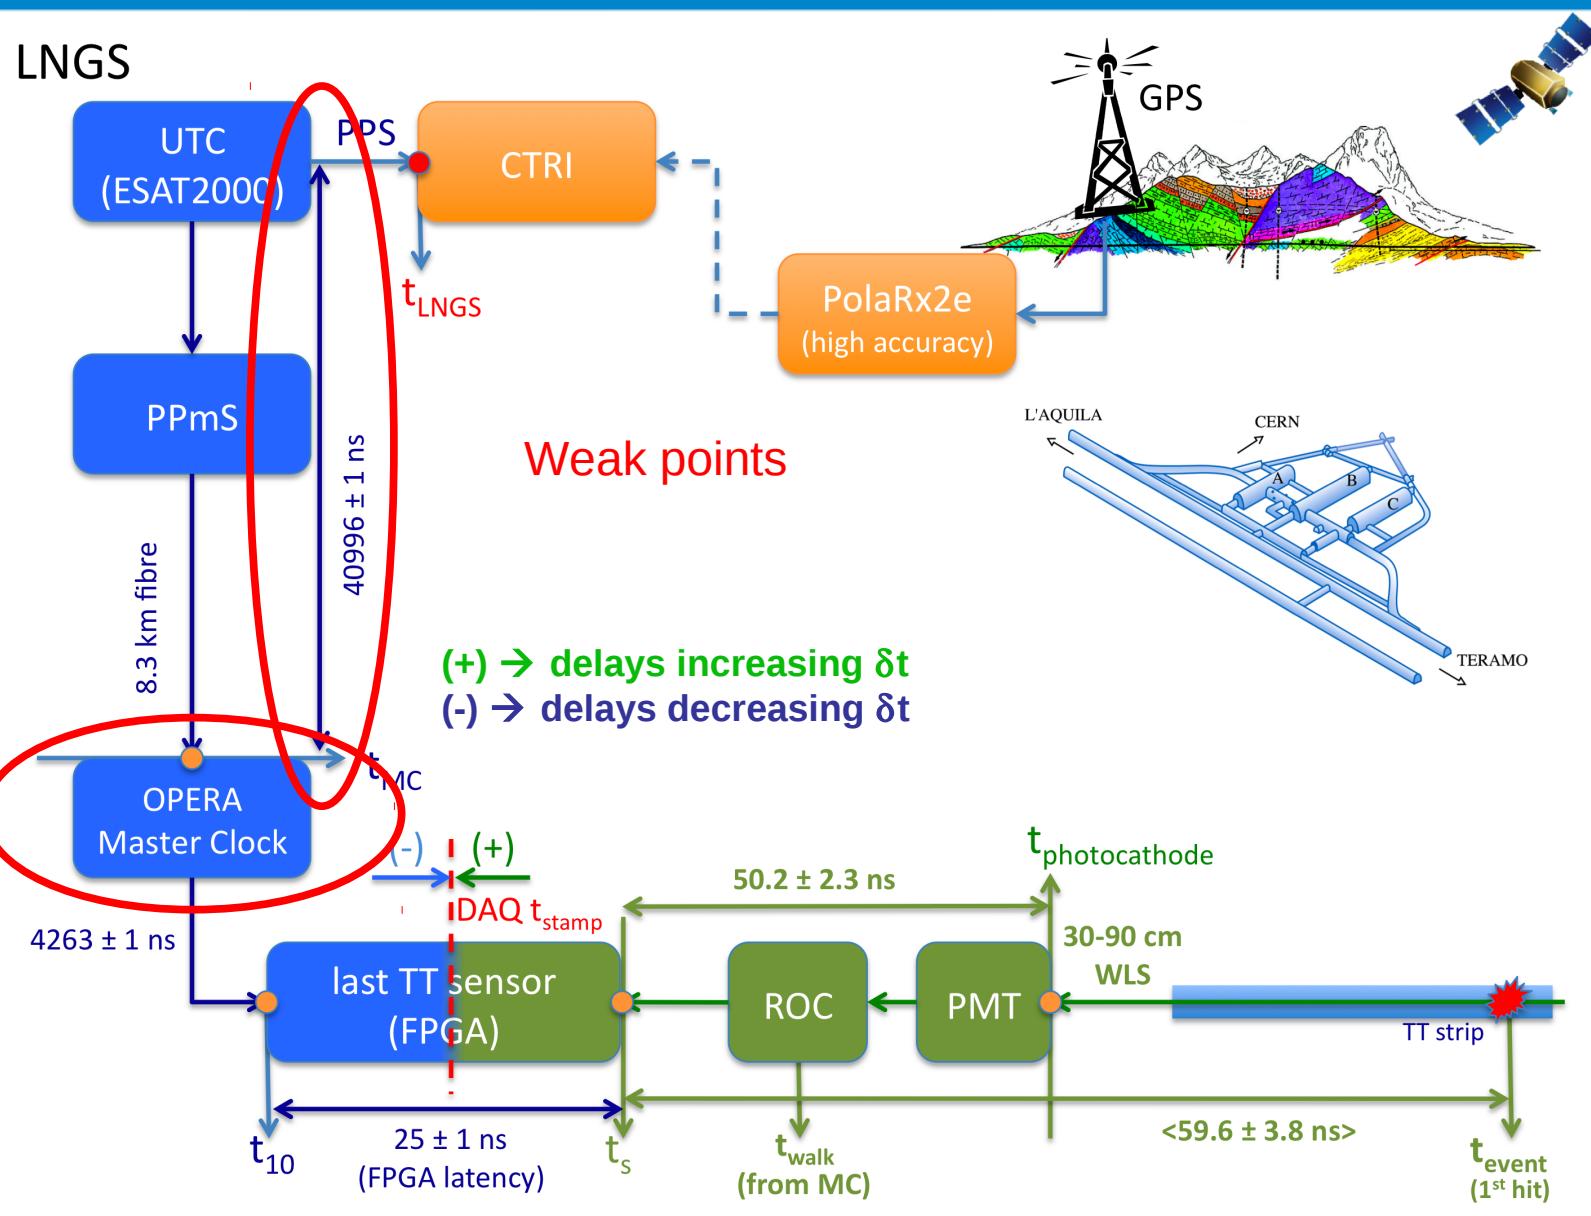

**CERN** measurements  
(taken in different periods) combined in  
the ETRF2000 European Global  
system, accounting for earth dynamics

Cross-check in June 2011:  
simultaneous CERN-LNFS  
measurement of GPS benchmarks

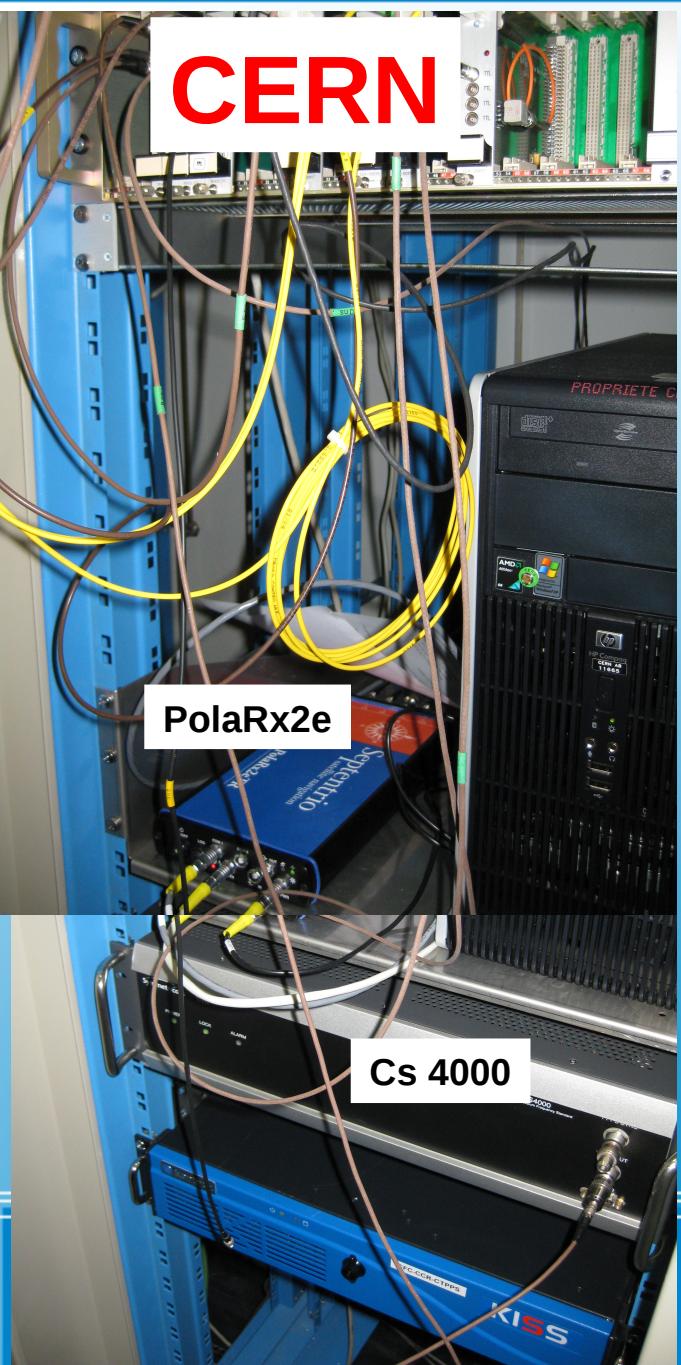

# Geodesy

Distance (BCT - OPERA reference frame) =  
 **$(731278.0 \pm 0.2)$  m**

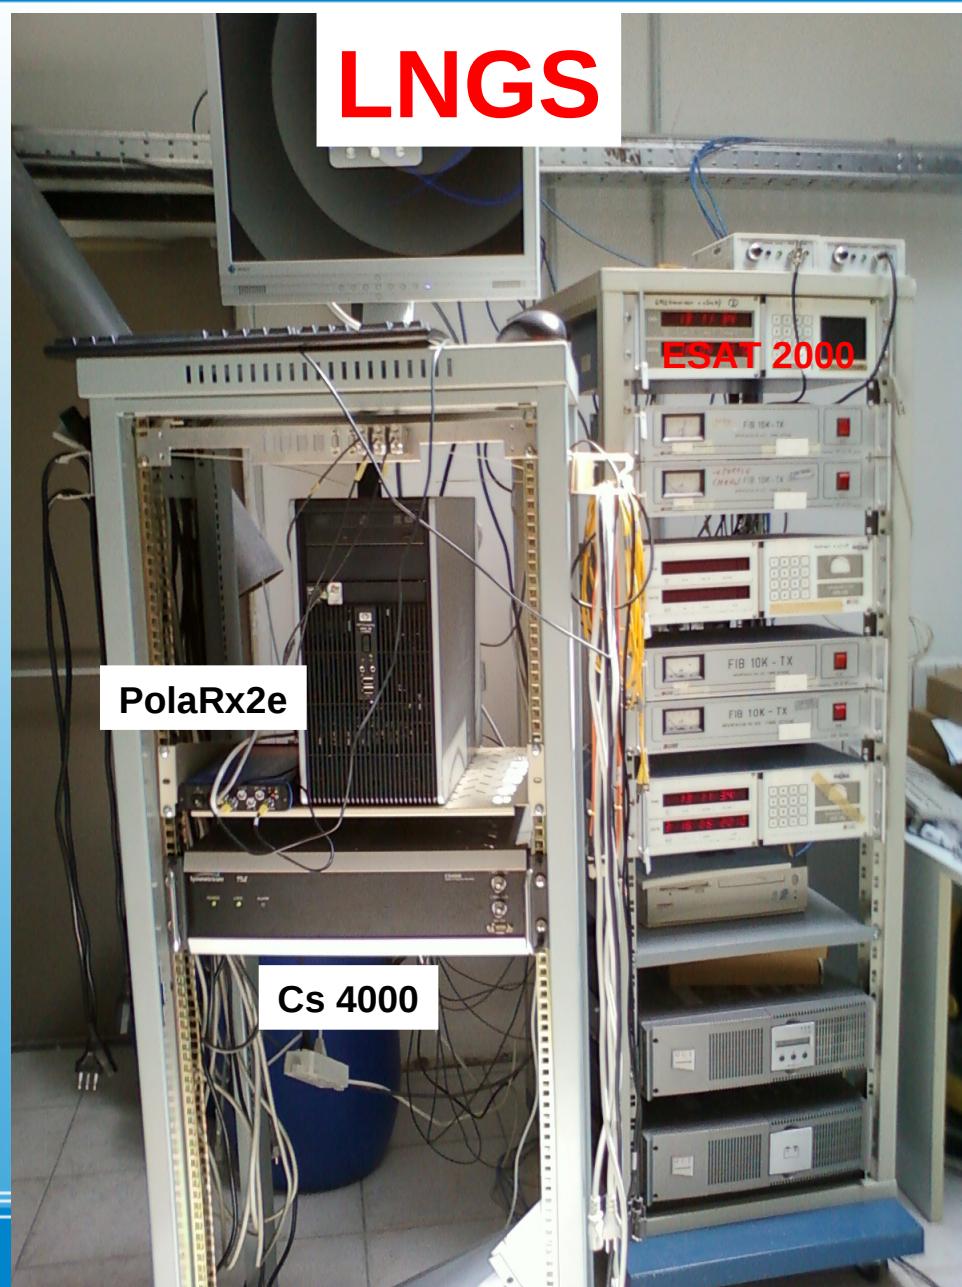

# Delay calibrations: LNGS side

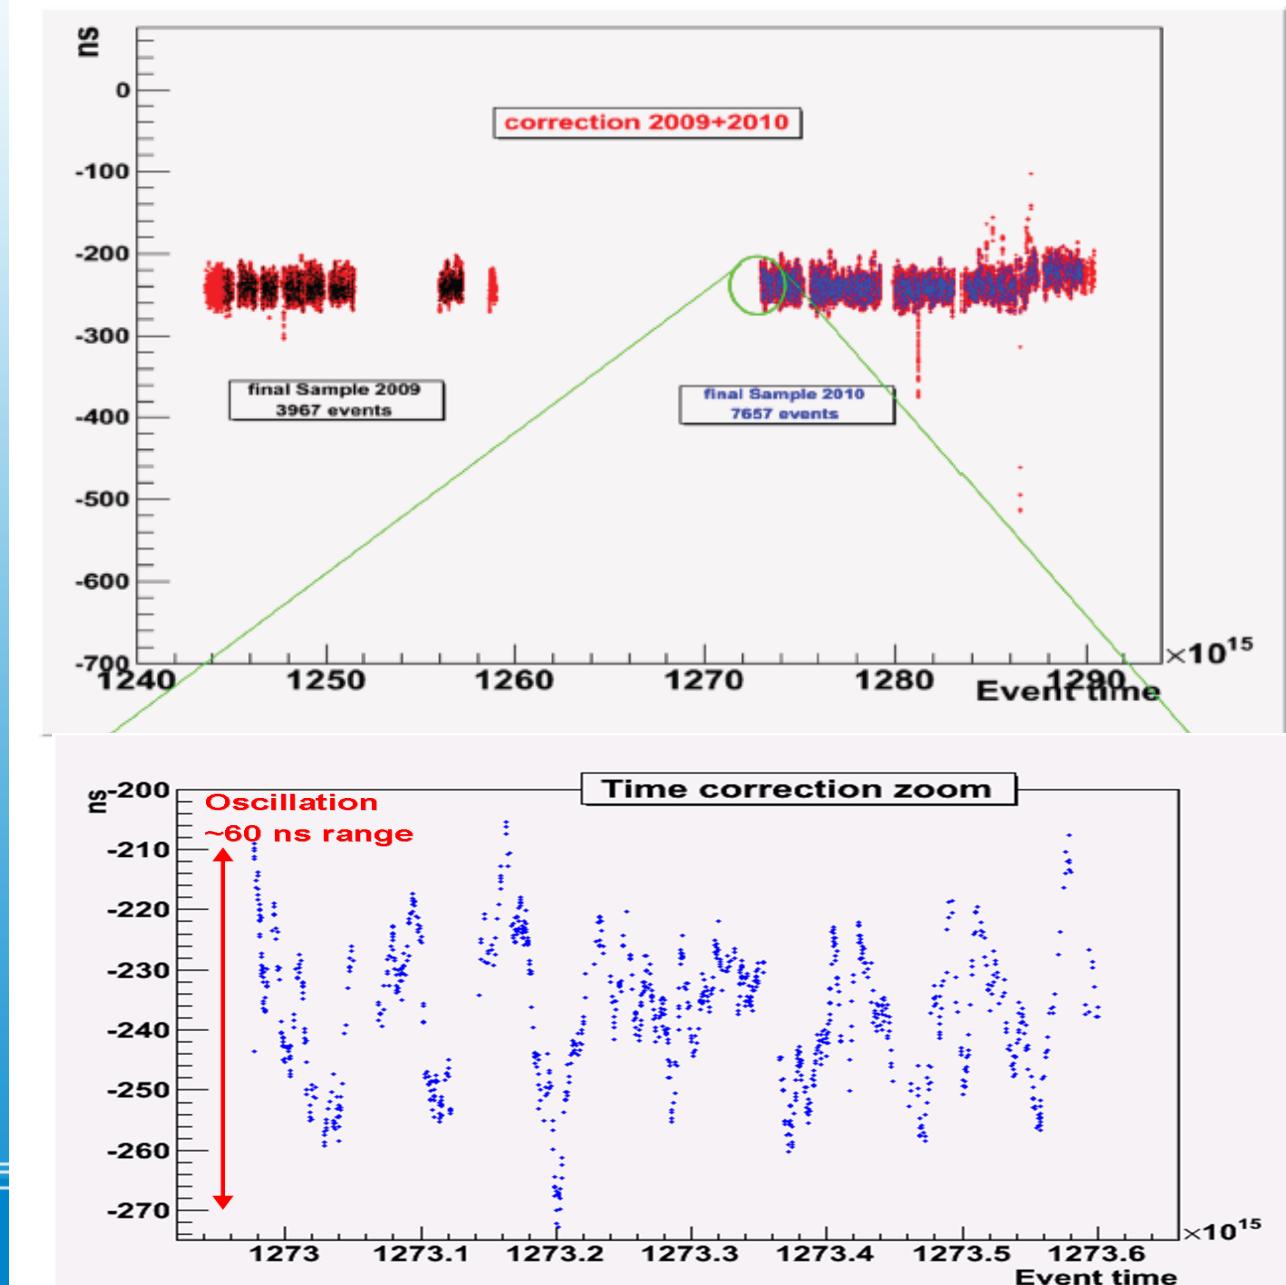

**PolaRx2e :**  
GPS receiver for time-transfer applications:

- frequency reference from Cs clock (**Cs-4000**)
- internal time tagging of 1PPS with respect to individual satellite observations
- off-line common-view analysis in CGGTTs format
- use ionosphere-free code (P3)

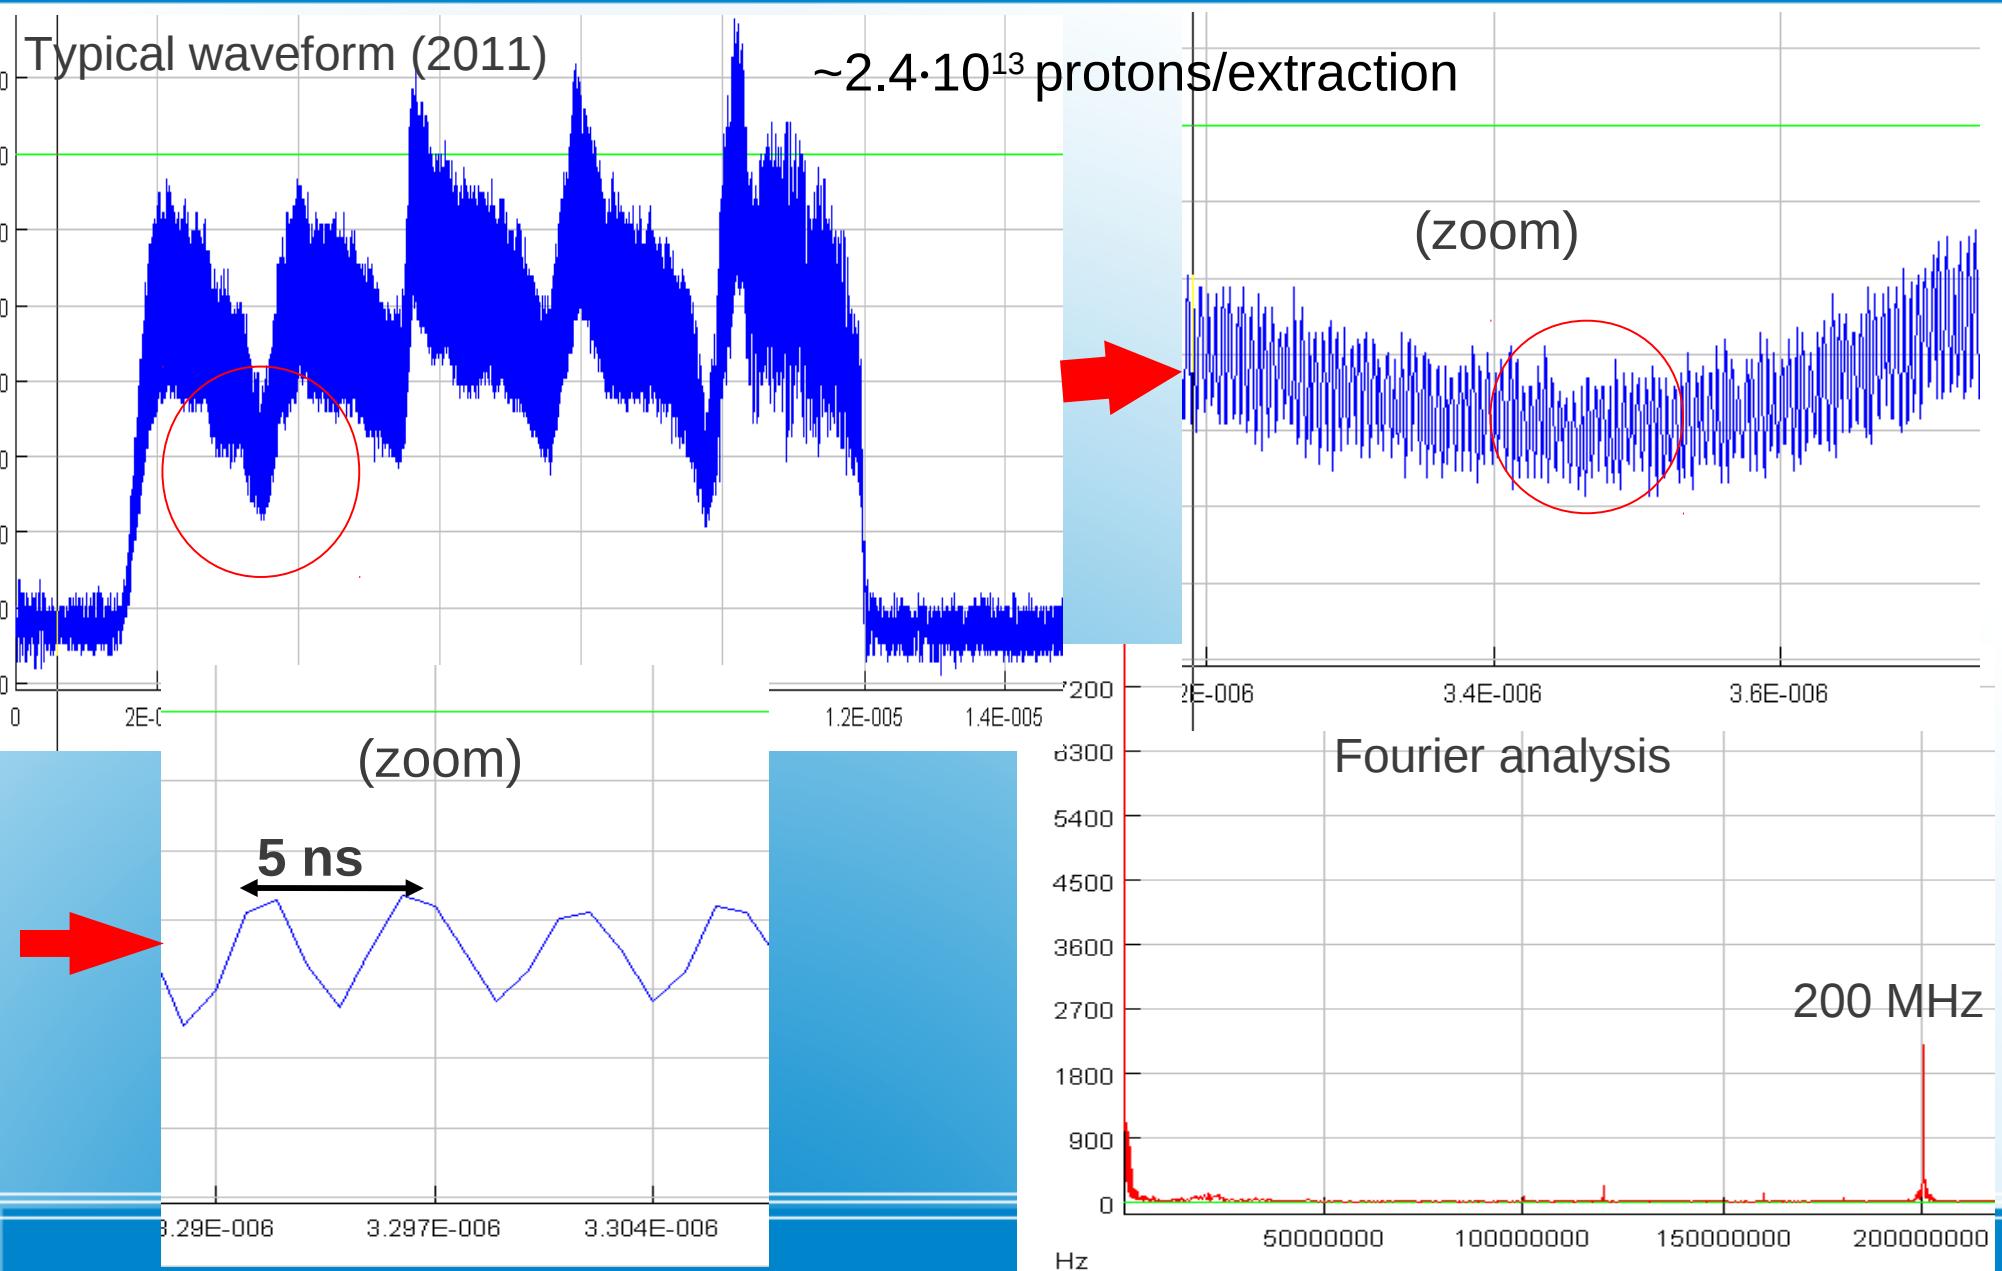

# Twin synchronization devices

Event-by-event correction  
From the GPS common  
view mode operations

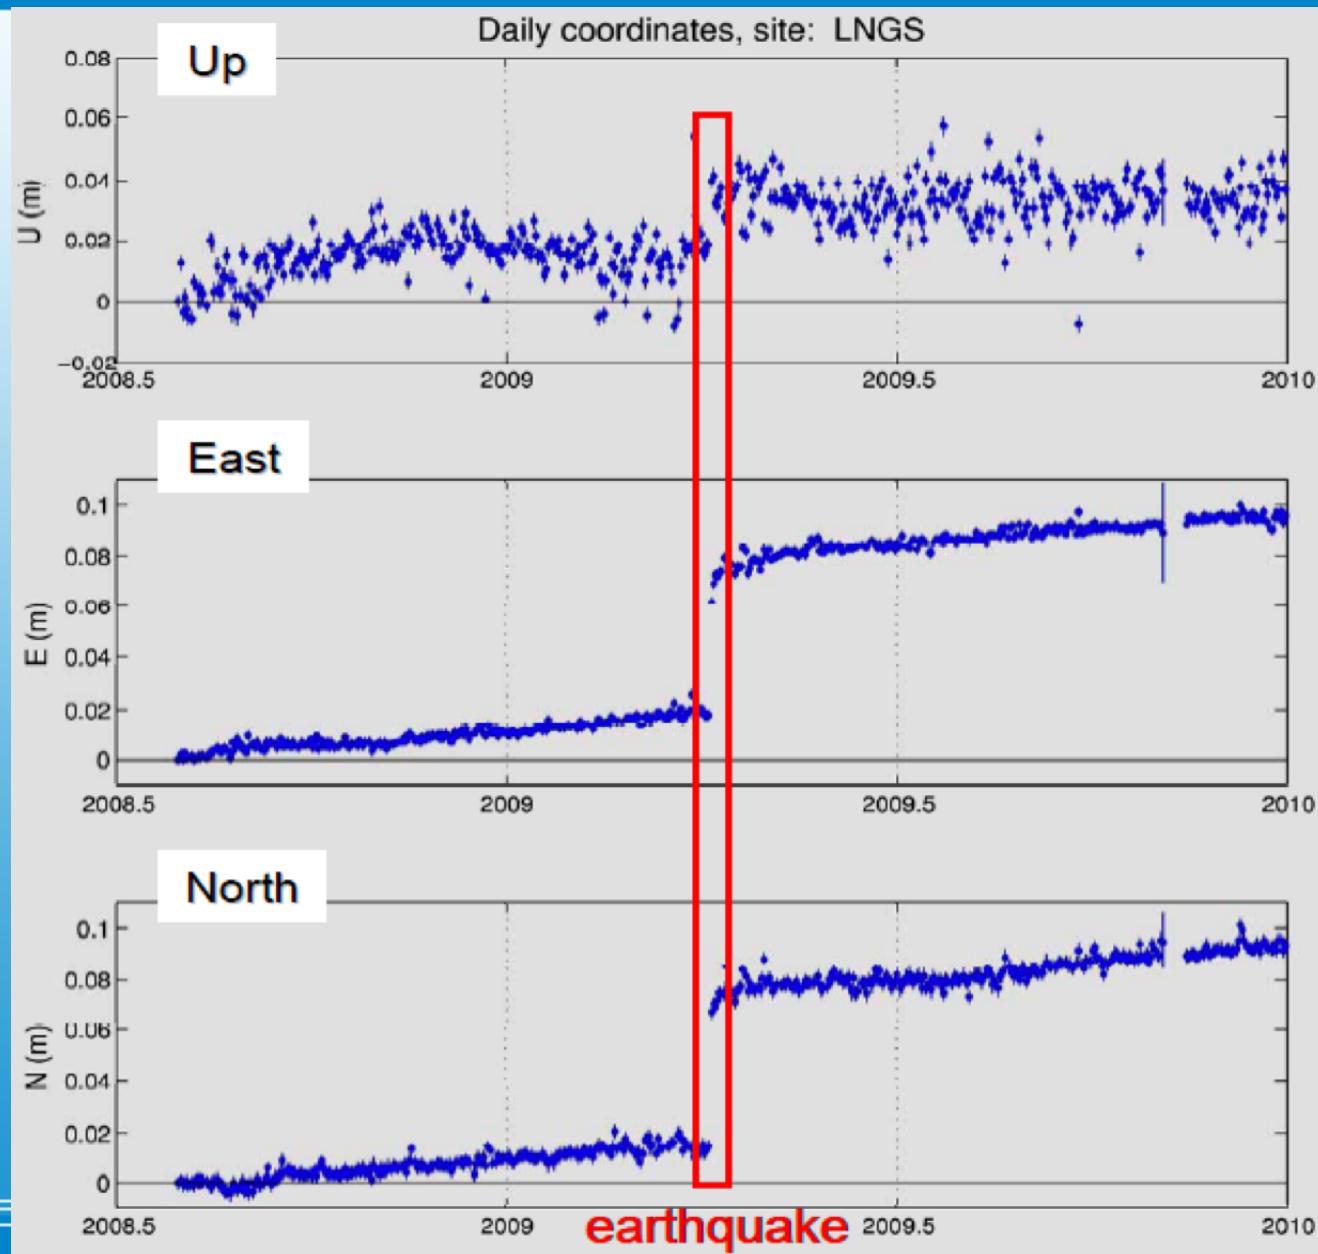

Result: TOF timelink correction

Single proton wave-form example

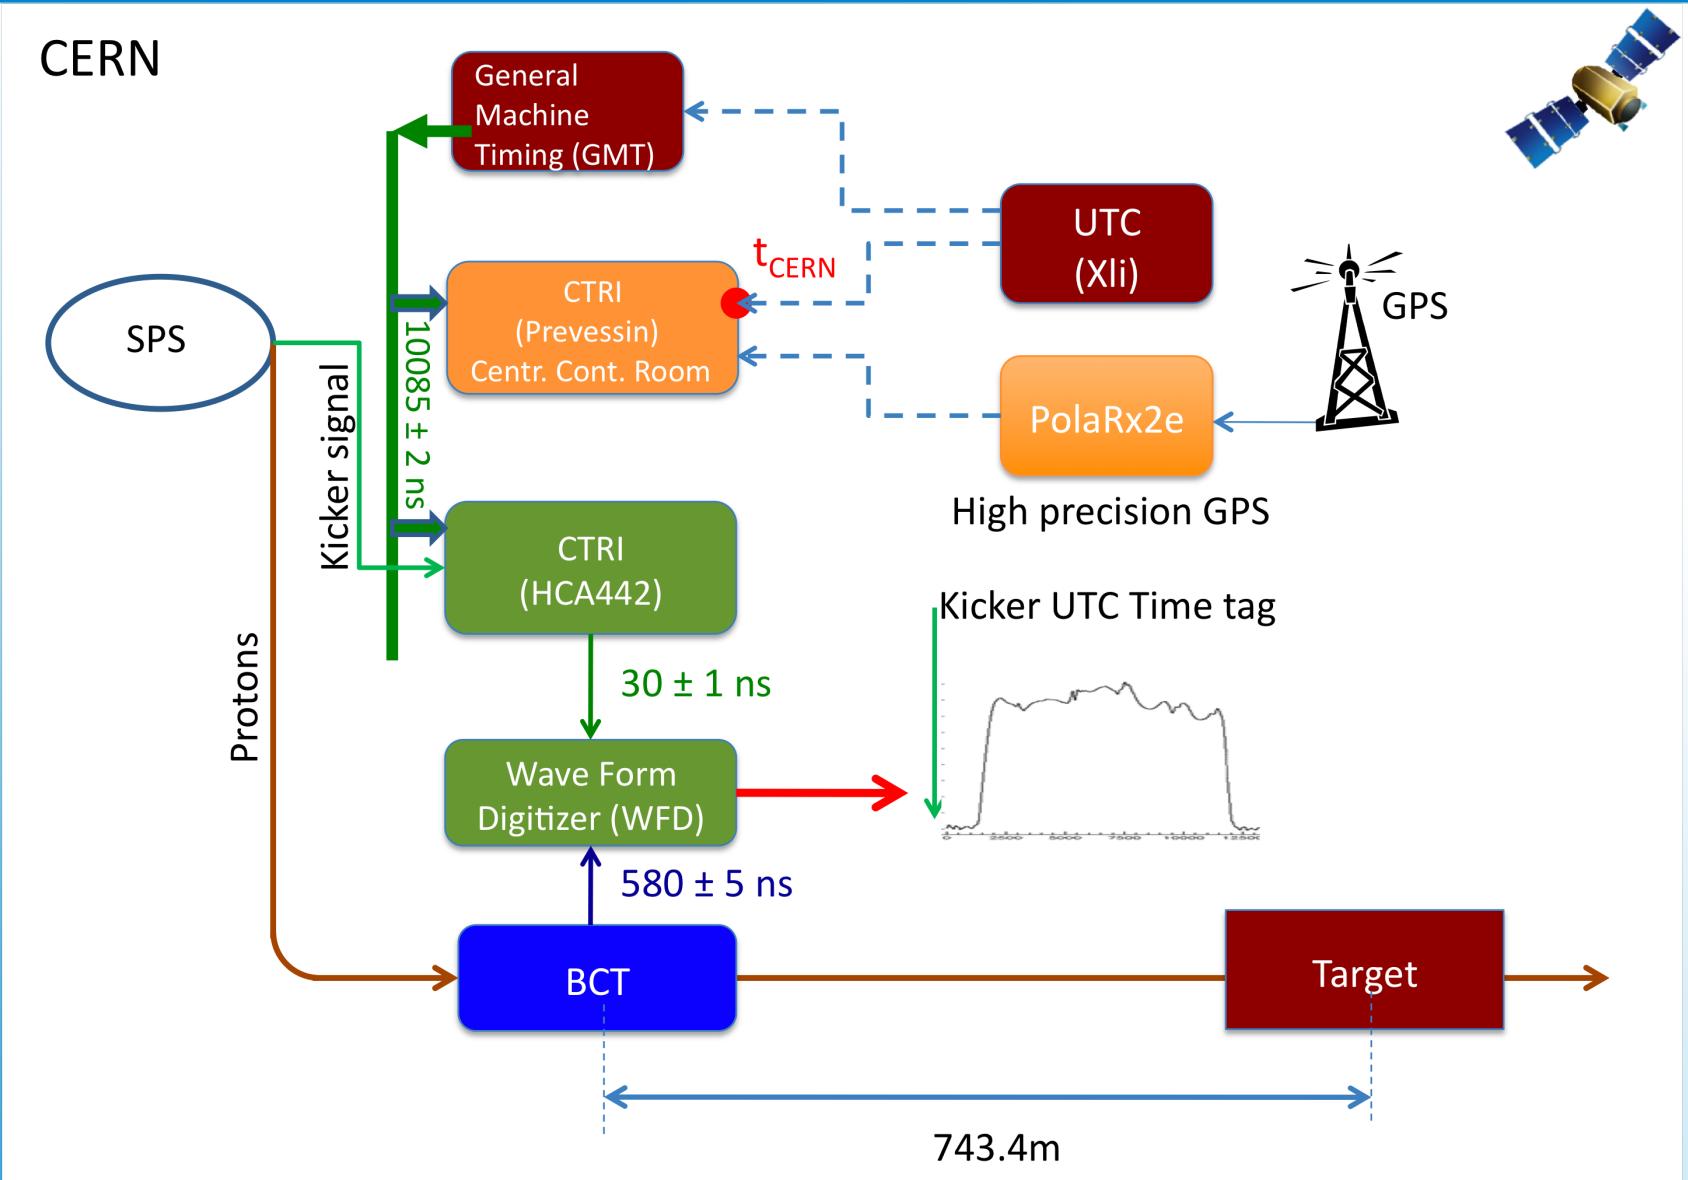

Long and short time scale phenomena visible:

- continental drift
- 2009 L'Aquila earthquake

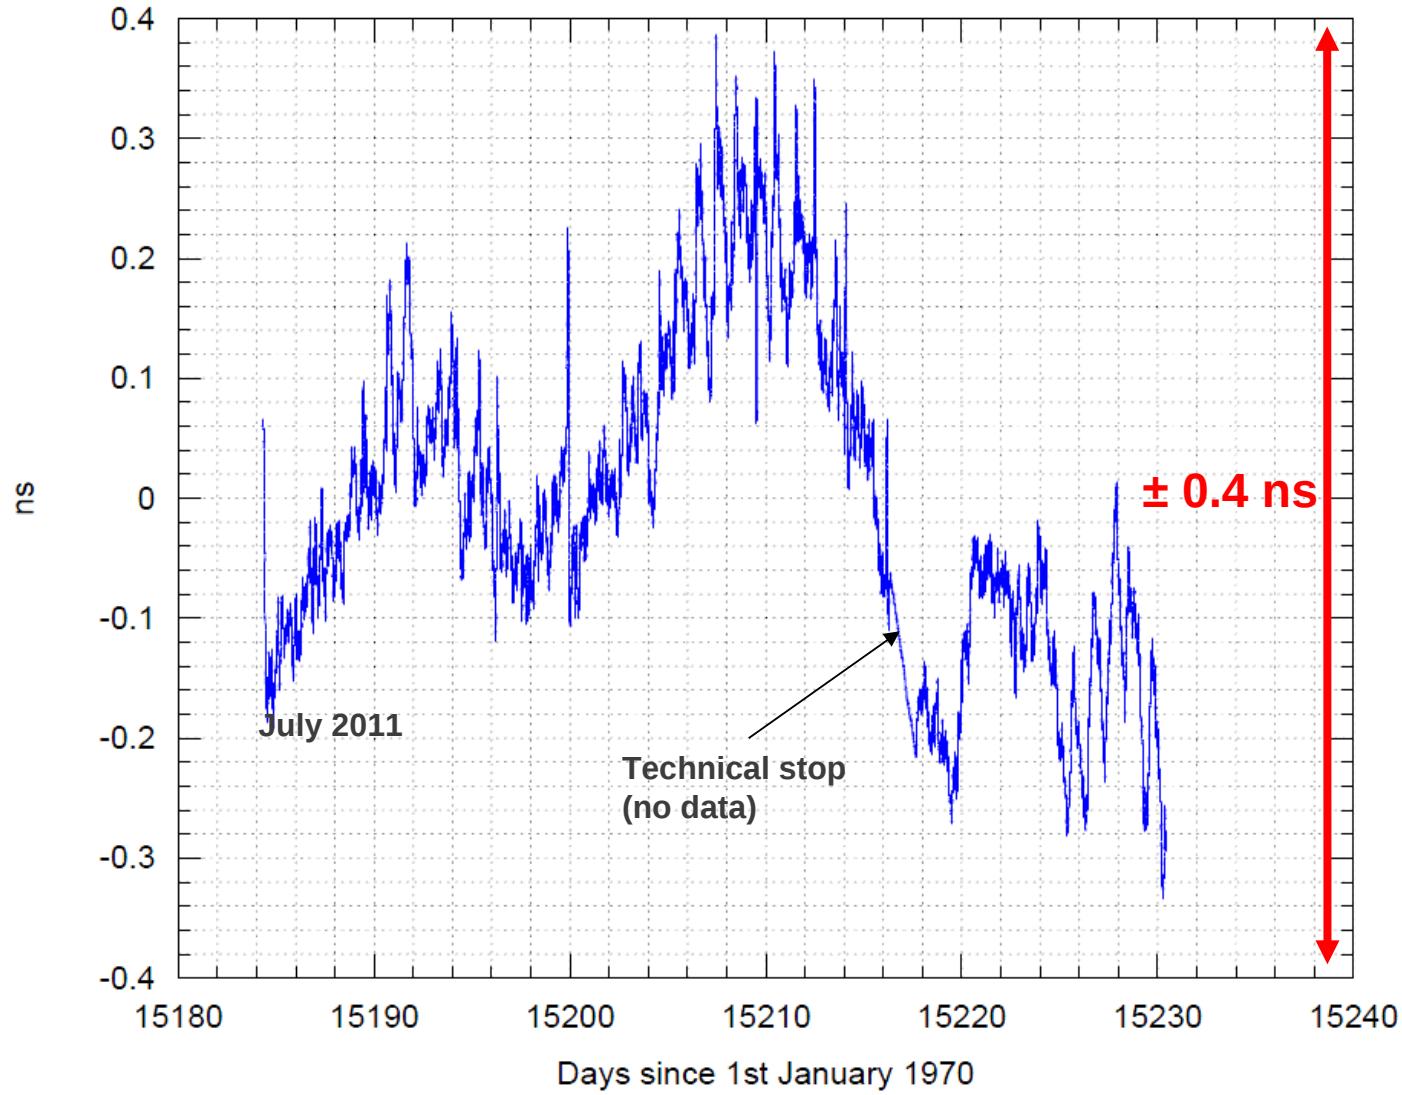

# LNGS position monitoring

CERN

# Delay calibrations: CERN side

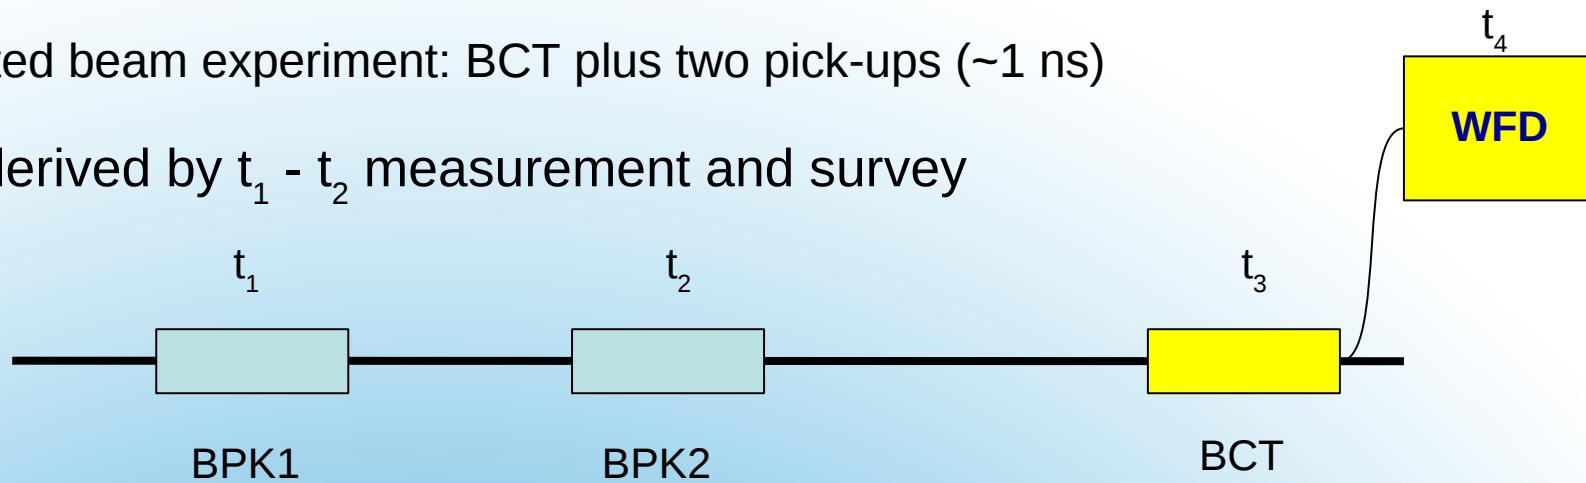

## variations w.r.t. nominal

Continuous two-way measurement of  
UTC delay at CERN

Dedicated beam experiment: BCT plus two pick-ups ( $\sim 1$  ns)

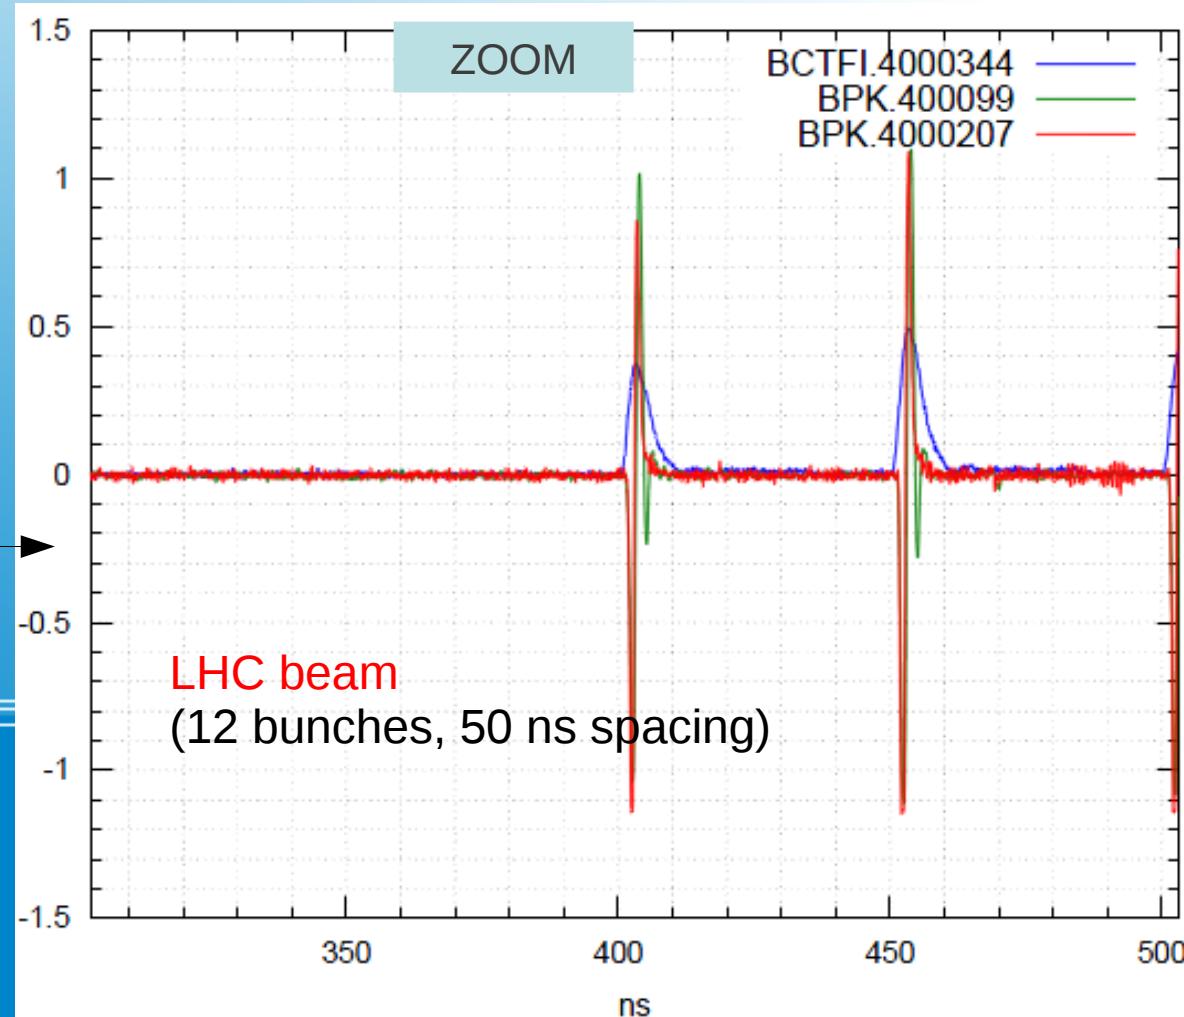

$t_3$  : derived by  $t_1 - t_2$  measurement and survey

$$\Delta t_{\text{BCT}} = t_4 - t_3 = (580 \pm 5) \text{ ns}$$

result: signals comparison after  
 $\Delta_{\text{BCT}}$  compensation

# BCT calibration

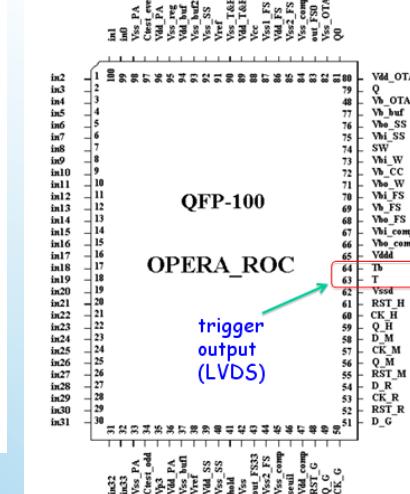

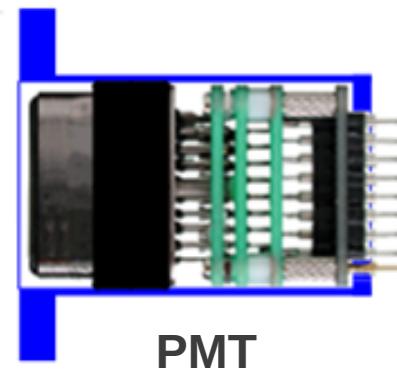

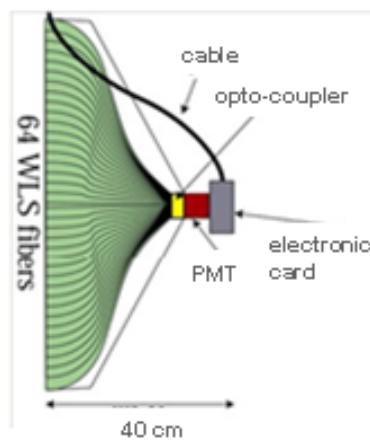

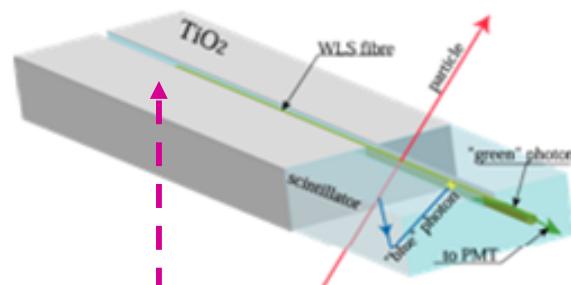

Scintillator + WLS fibers

signal

PMT

analog Front End chip (ROC)

FPGA

Picosecond Injection Laser  
(PiLas)

picosecond UV laser excitation:

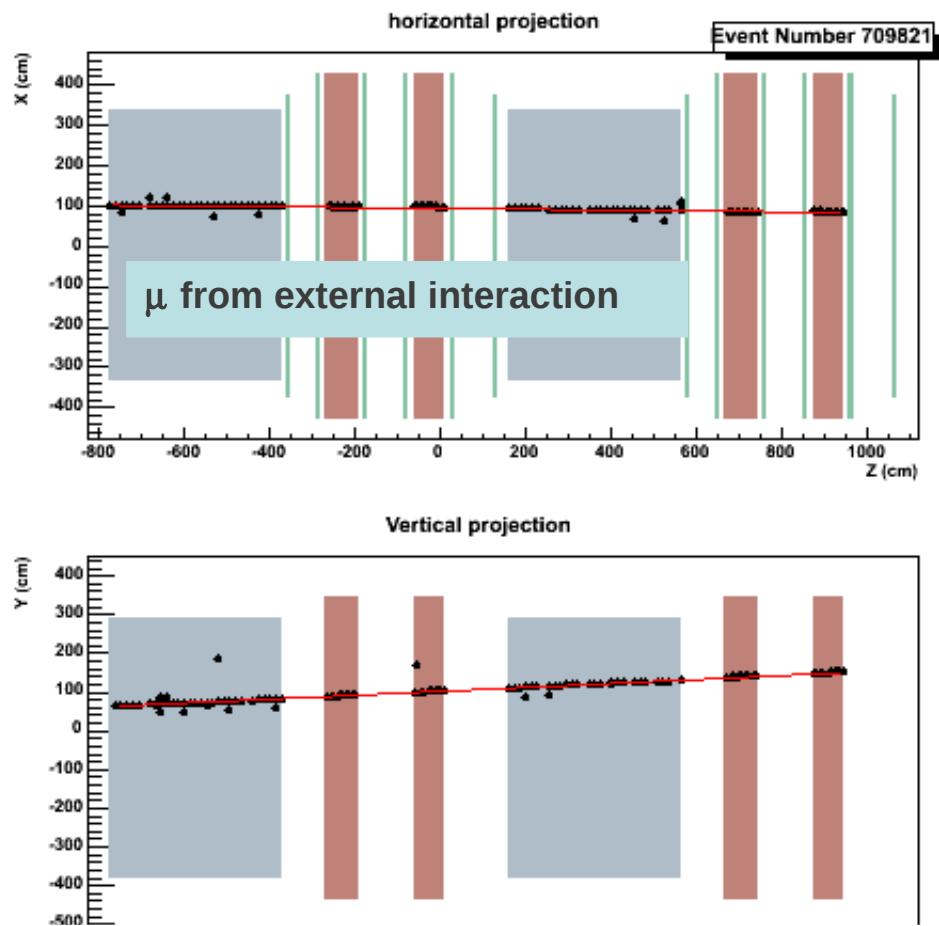

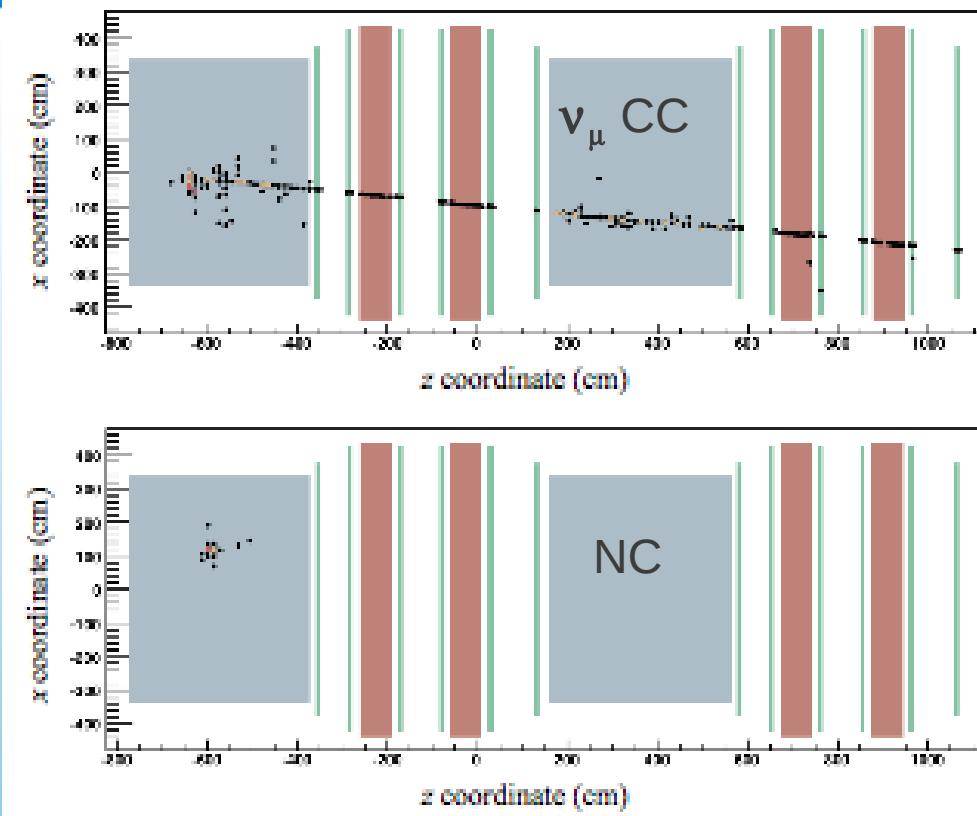

→ delay from photo-cathode to FPGA input:  $(50.2 \pm 2.3)$  ns

→ average event time response:  $(59.6 \pm 3.8 \text{ (sys.)})$  ns

including event position, pulse height dependence, ROC time-walk, DAQ quantization effects with simulations

# TT time response measurement

First TT hit used as "stop"  
and translated in time to a common reference point (assuming c)  
Internal/External: 7235/7988 events with 2009-2010-2011 CNGS runs ( $\sim 10^{20}$  pot)  
External events timing checked with full simulation → 2 ns systematic uncertainty

# Internal and external events

$$\delta t = \text{TOF}_c - \text{TOF}_\nu$$

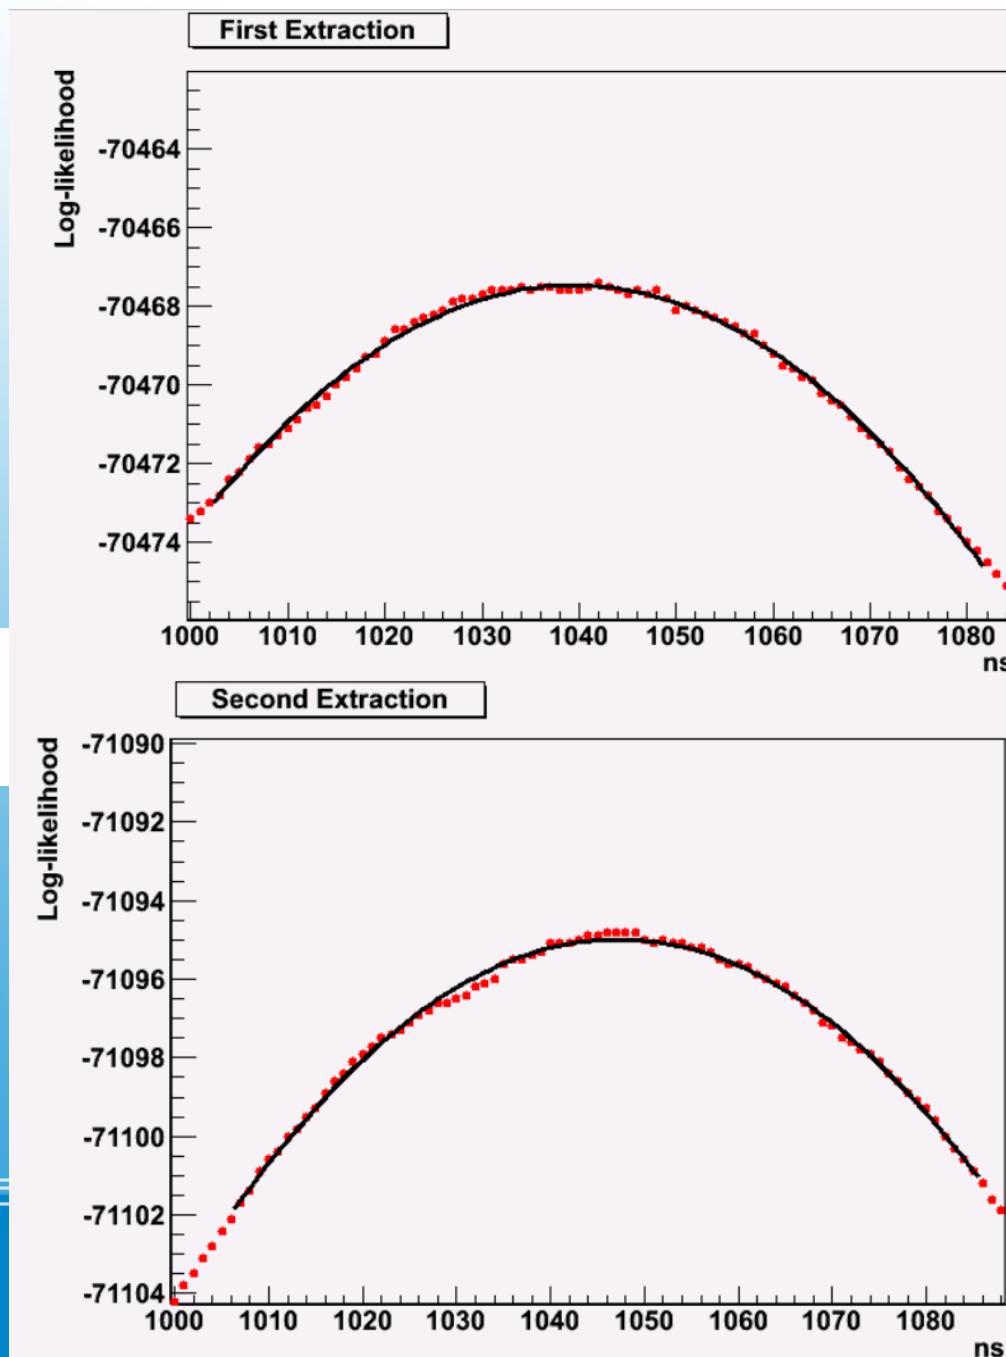

positive (negative)  $\delta t \rightarrow$   
 $\nu$  arrives earlier (later) than light

Unbinned Log-Likelihood  
maximised over  $\delta t$ :

$$L_k(\delta t_k) = \prod_j w_k(t_j + \delta t_k) \quad k=1,2 \text{ extractions}$$

Statistical error evaluated from  
log likelihood curves

## Analysis method

1) Coherence among CNGS runs/extractions

2) No hint for day-night

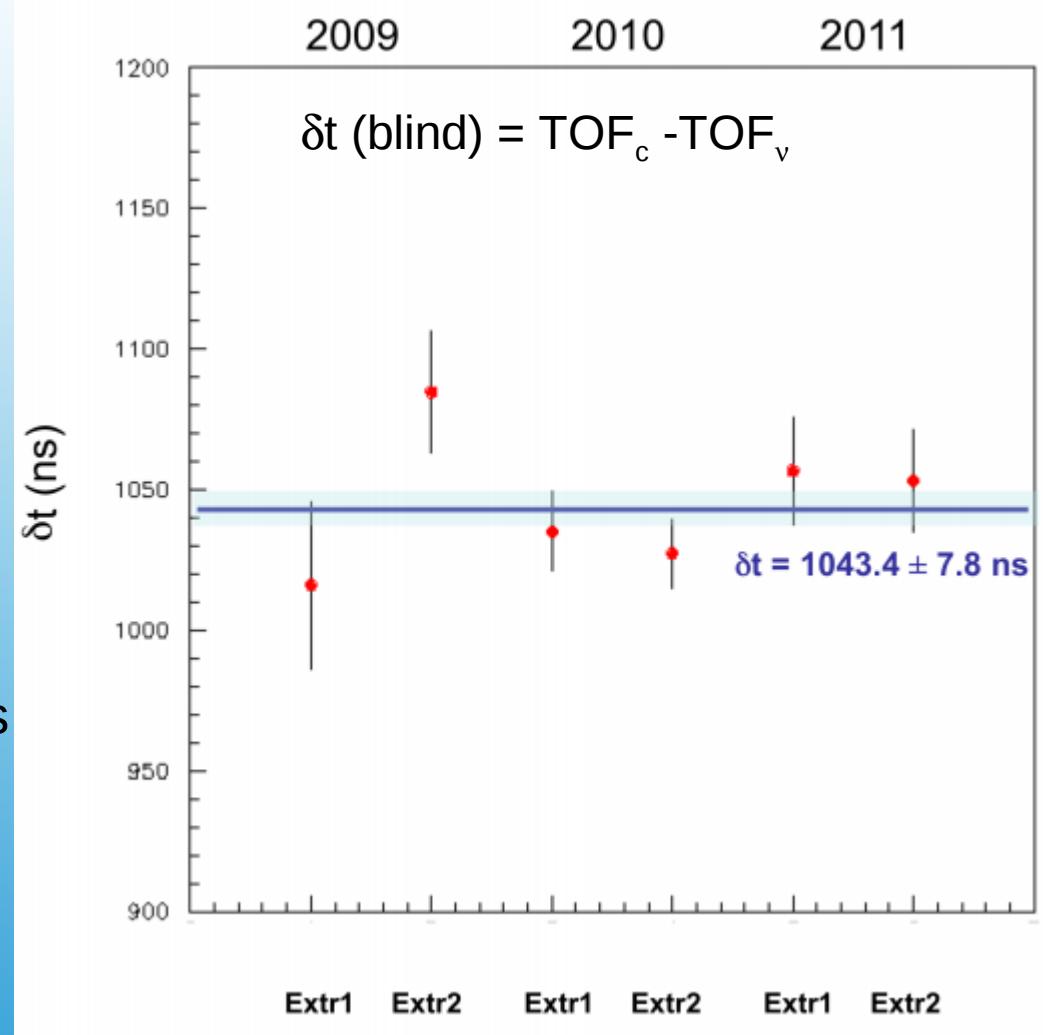

$$|day-night| = 16.4 \pm 15.8 \text{ ns}$$

3) or seasonal effects:  
 $|(\text{spring+fall}) - \text{summer}|: 15.6 \pm 15.0 \text{ ns}$

4) Internal vs external events:

$$\text{All: } 1043.4 \pm 7.8 \text{ ns}$$

$$\text{Internal: } 1045.1 \pm 11.3 \text{ ns}$$

## Cross-checks

## Timing and baseline corrections

	Blind analysis (ns) 2006	Final analysis (ns) 2011	Correction (ns)
Baseline	2440079.6	2439280.9	
Earth rotation		2.2	
Correction baseline			-796.5
<b>CNGS delays:</b>

Time-link	0	-2.3	
Correction GPS			350.7
<b>Total correction</b>			<b>-985.6</b>

## Systematic uncertainties

Systematic uncertainties	ns	Error distribution
Baseline (20 cm)	0.67	Gaussian
Decay point	0.2	Exponential (1 side)
Interaction point	2.0	Flat (1 side)
UTC delay	2.0	Gaussian
LNGS fibres	1.0	Gaussian
DAQ clock transmission	1.0	Gaussian
FPGA calibration	1.0	Gaussian
FWD trigger delay	1.0	Gaussian
CNGS-OPERA GPS synchronisation	1.7	Gaussian
MC simulation for TT timing	3.0	Gaussian
TT time response	2.3	Gaussian
BCT calibration	5.0	Gaussian
<b>Total systematic uncertainty</b>	<b>-5.9, +8.3</b>	

$$\delta t = \text{TOF}_c - \text{TOF}_v = (1043.4 - 985.6) \text{ ns} = (57.8 \pm 7.8 \text{ (stat.)}^{+8.3}_{-5.9} \text{ (sys.)}) \text{ ns}$$

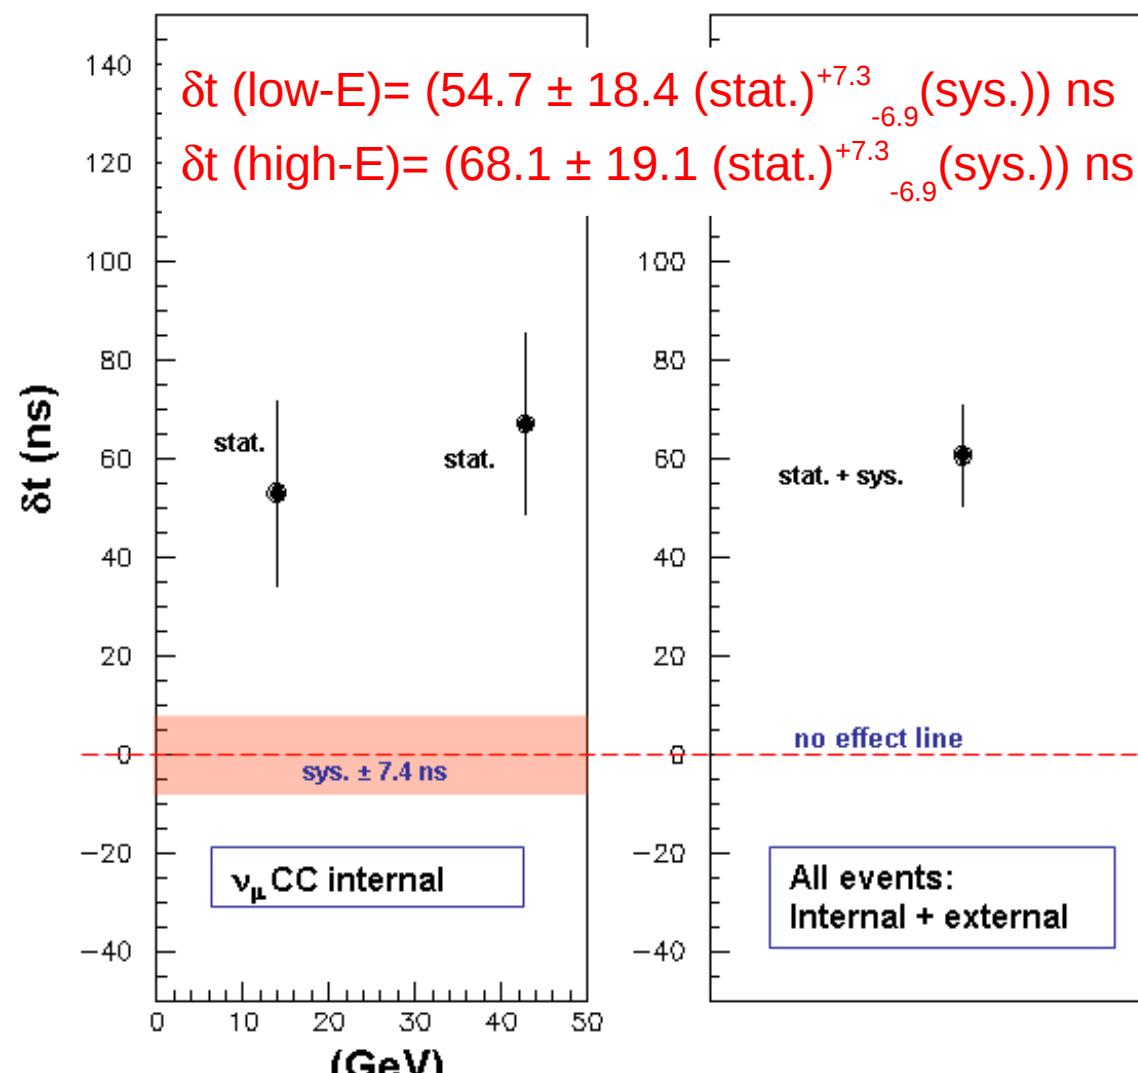

Opening the box: result

**Reconstructed Event Energy**

Only internal muon-neutrino CC events used (5199 events)

$$\delta t = (61.1 \pm 13.2 \text{ (stat.)}^{+7.3}_{-6.9} \text{ (sys.)}) \text{ ns}$$

No indication for energy dependence within the present sensitivity in the explored energy domain

# Energy dependence

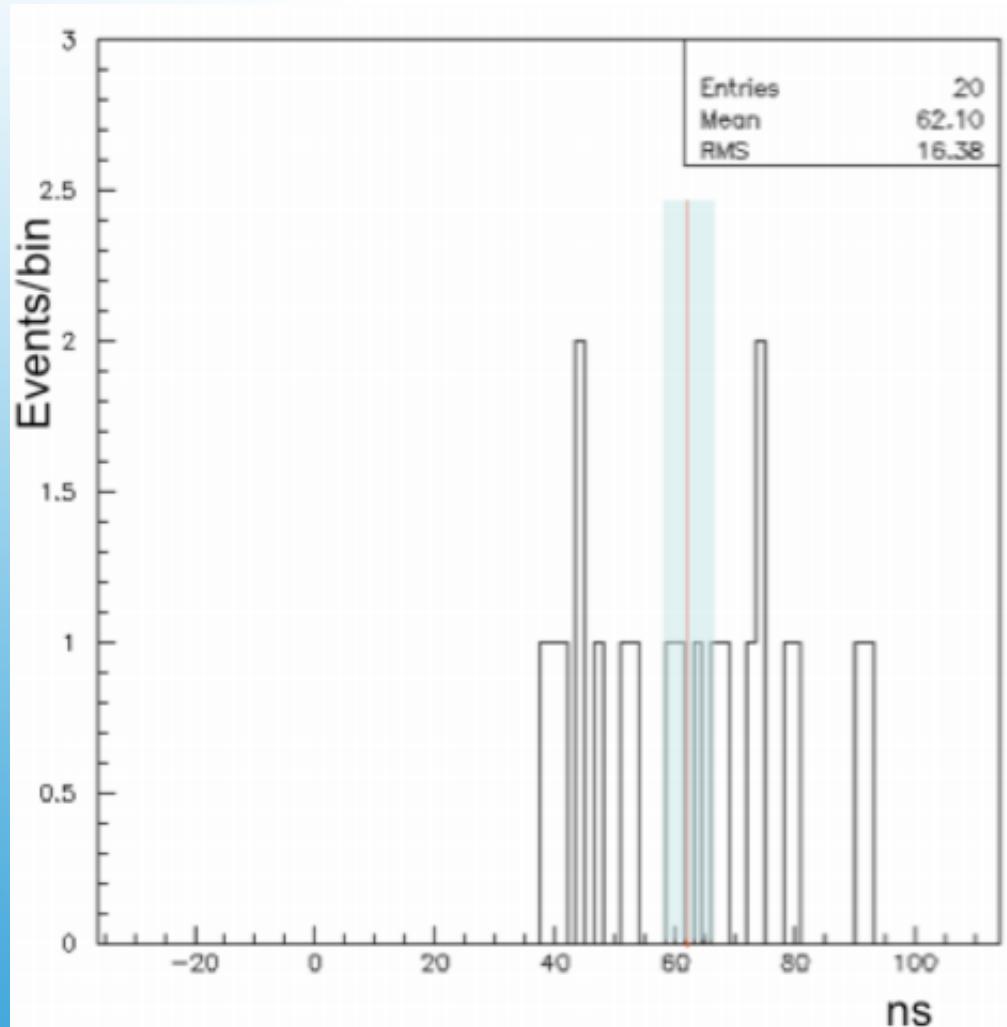

$$\delta t = (62.1 \pm 3.7) \text{ ns}$$

with original beam timing :  $57.8 \pm 7.8$  ns

Main contributions to the RMS (16.4 ns):

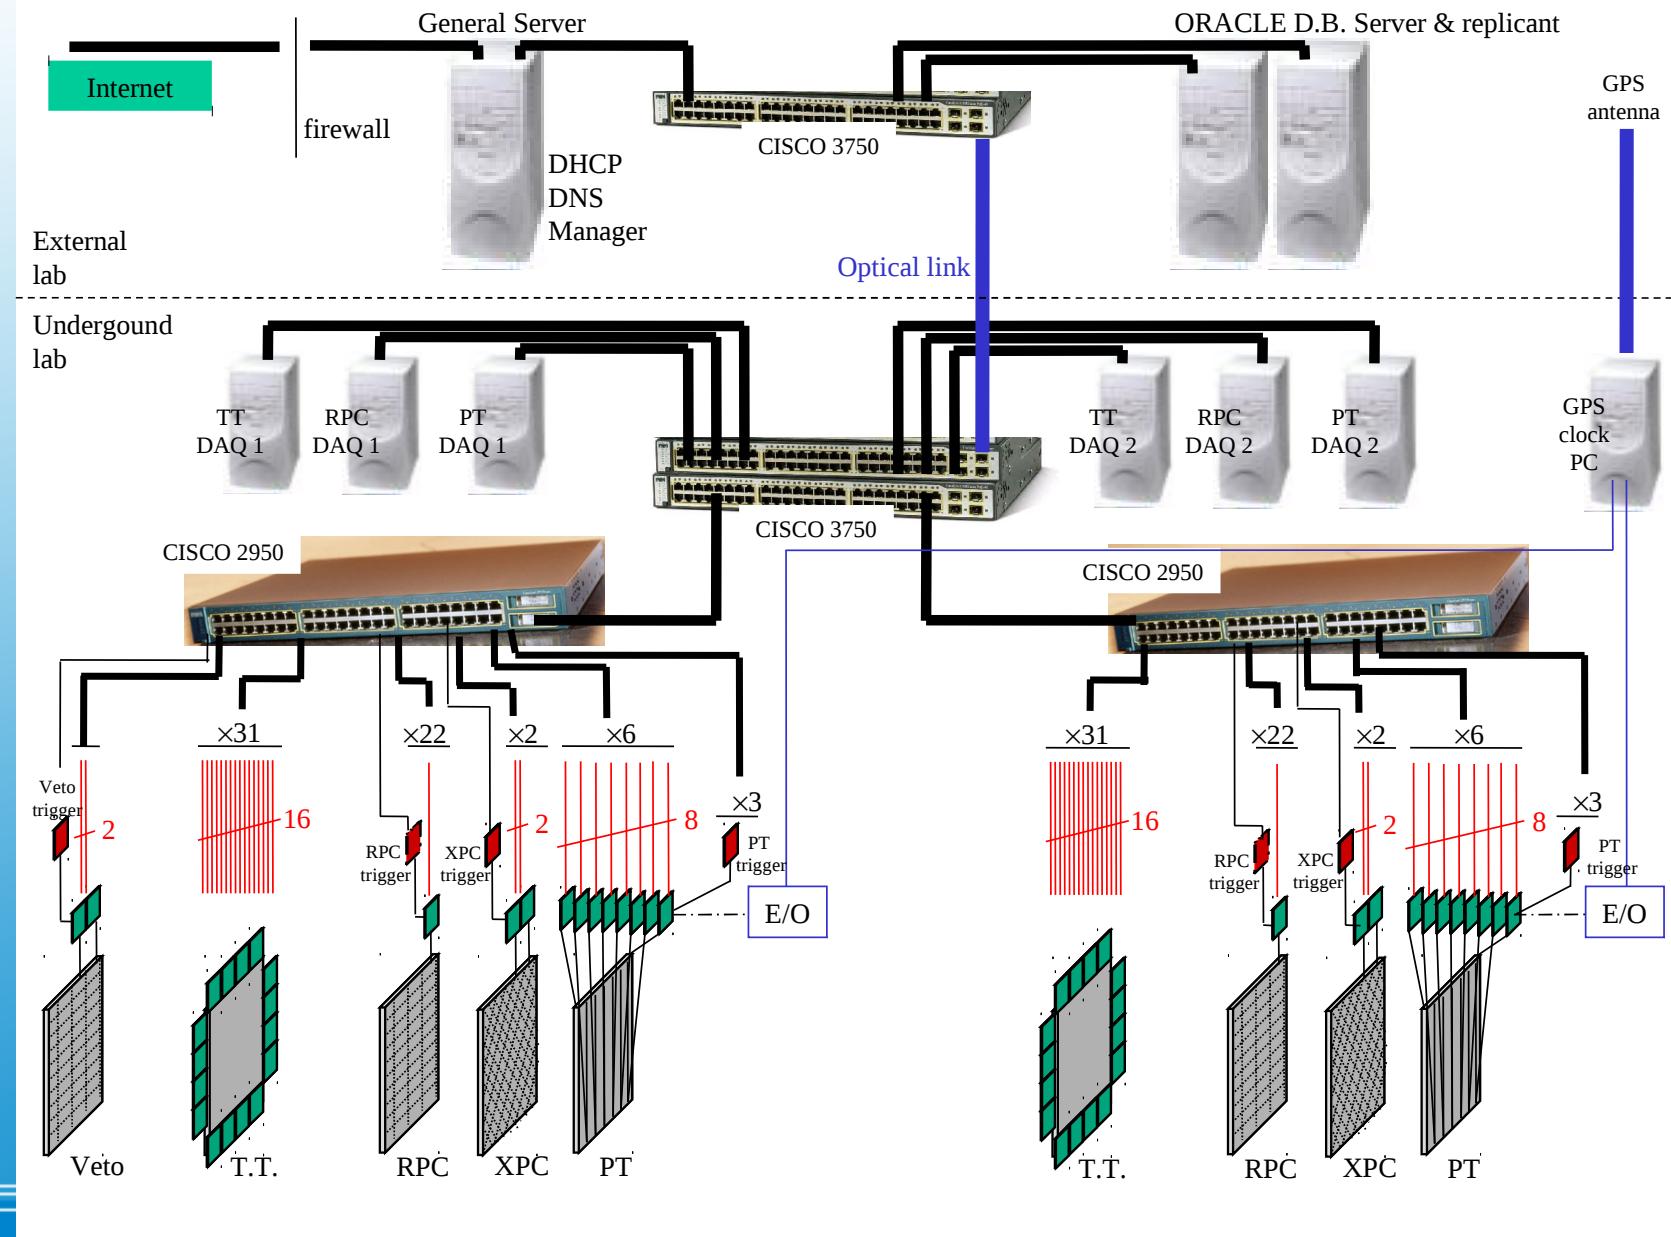

- TT response (7.3 ns)
- DAQ time granularity (10 ns full width)
- $\pm 25$  ns flat jitter
- The dominant  $\pm 25$  ns term is related to the tagging of the GPS signal by the 20 MHz OPERA master clock (RMS =  $50$  ns/ $\sqrt{12}$  = 14.4 ns).

The statistical accuracy on the average  $\delta t$  is already as small as 3.7 ns with only 20 events (collected in 15 days).

# Bunched-beam result

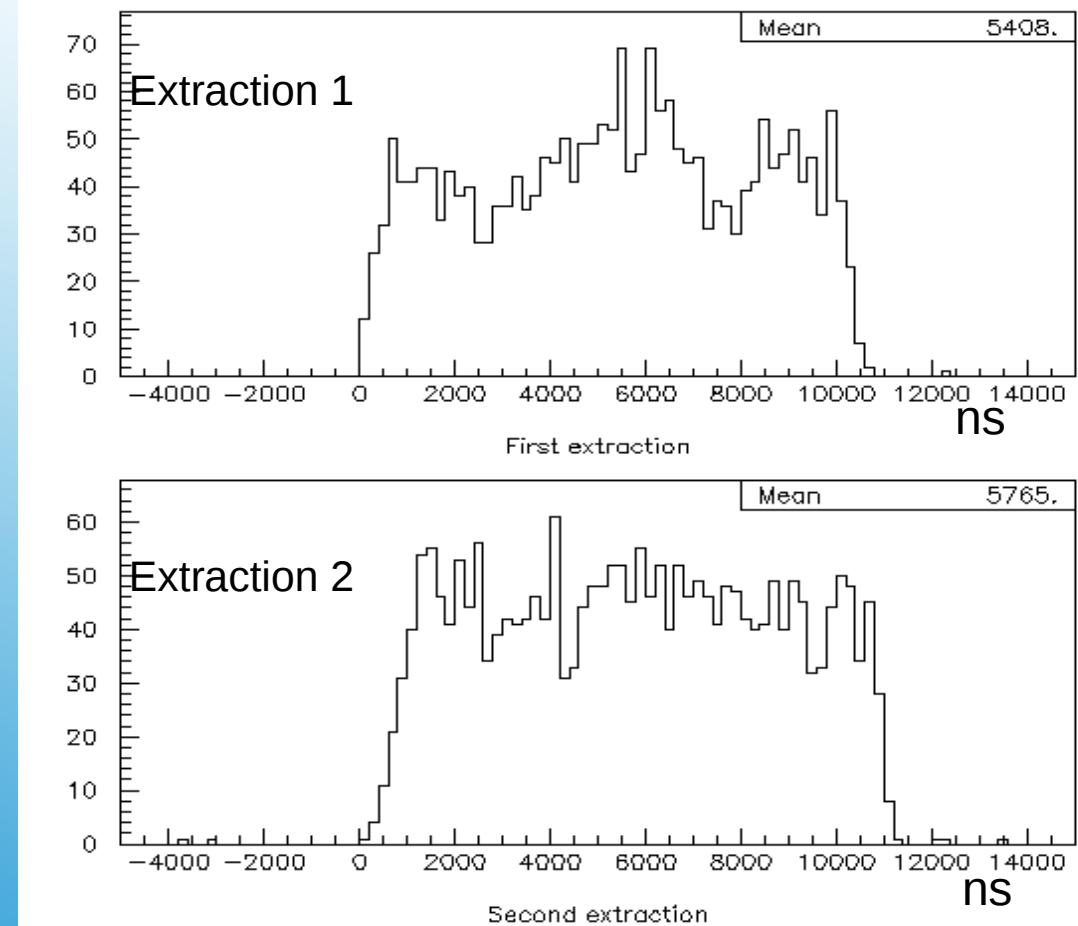

- Trigger-less
- 1200 asynchronous FE nodes
- Gigabit ethernet network

# OPERA read-out scheme

Typical neutrino event time distributions w.r.t kicker magnet trigger pulse =>

- Not flat
- Different timing for the two extractions

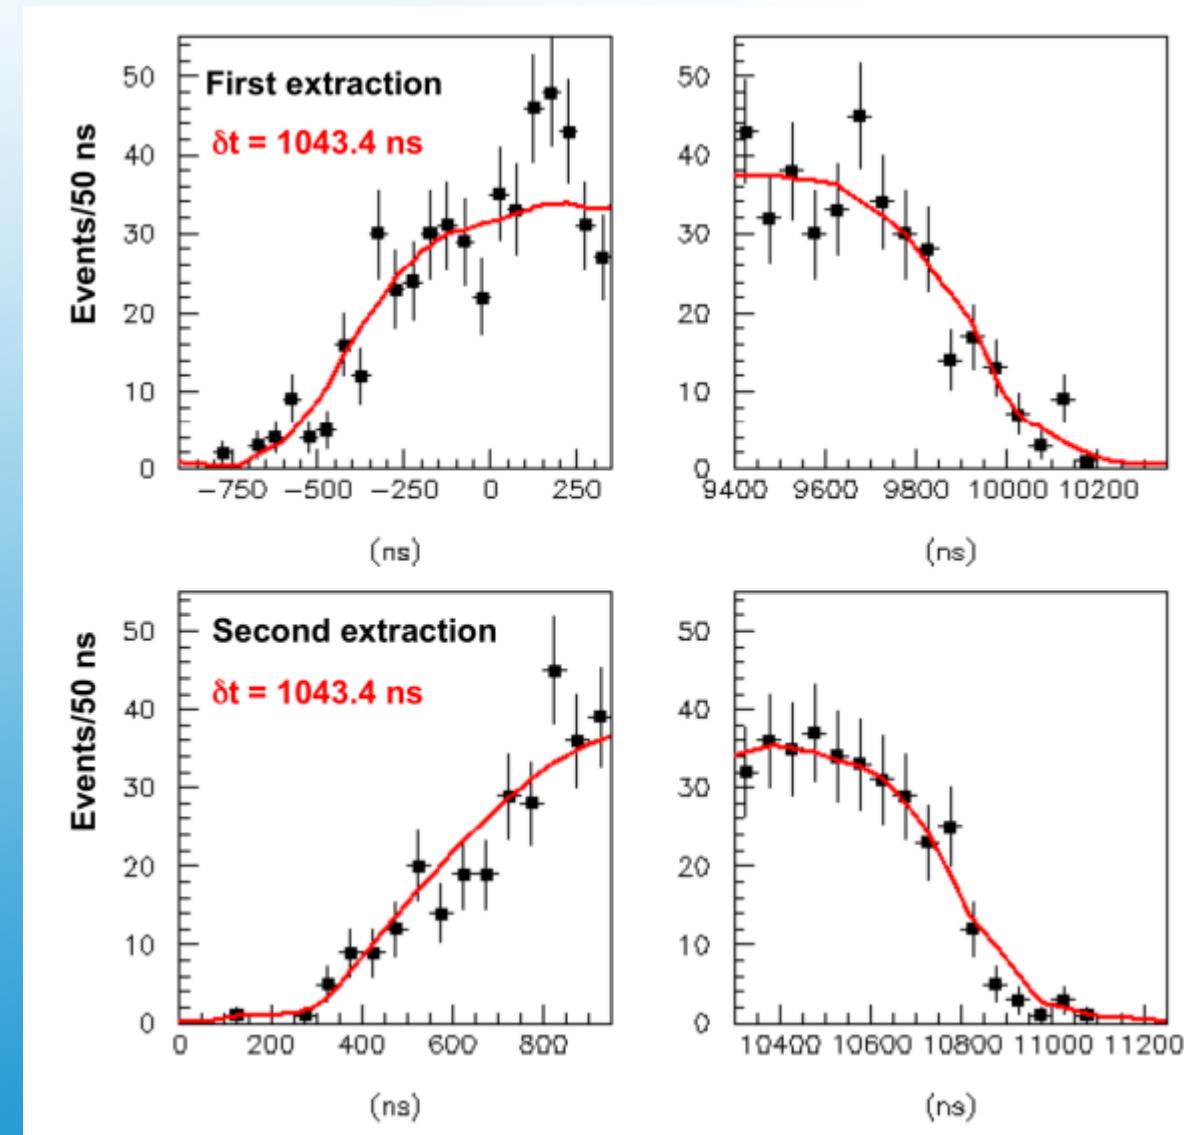

→ Need to measure precisely the proton spills

From selection to the velocity measurement

- FNAL experiment ([Phys. Rev. Lett. 43 \(1979\) 1361](#))  
 $v_\mu$  ( $E_\nu > 30$  GeV) short baseline experiment.  
 $|v-c|/c \leq 4 \cdot 10^{-5}$  (comparison of  $v_\mu$  and  $\mu$  velocities).
- Supernova SN1987A (e.g. [Phys. Lett. B 201 \(1988\) 353](#))  
electron (anti)  $\nu$ ,  $E \sim 10$  MeV, 168.000 light years baseline.  
 $|v-c|/c \leq 2 \cdot 10^{-9}$  ( $v$  and light arrival time).
- MINOS ([Phys. Rev. D 76 072005 2007](#))  
 $v_\mu$ ,  $E_\nu \sim 3$  GeV with a tail above 100 GeV. 730 km baseline.  
 $(v-c)/c = (5.1 \pm 2.9) \cdot 10^{-5}$ ,  $1.8\sigma$ , ( $v_\mu$  at near and far site)

Cross-check done in June 2011: simultaneous CERN-LNGS measurement of GPS benchmarks

Distance (BCT - OPERA reference frame) = **(731278.0 ± 0.2) m**

# Combination with CERN geodesy

$$L(\delta t) = \prod_j w_j(t_j + \delta t)$$

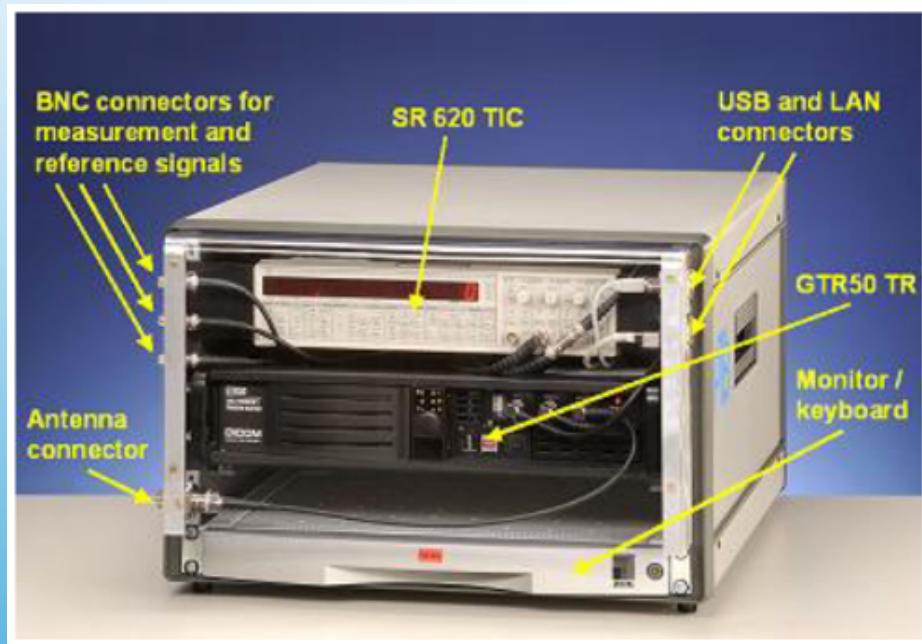

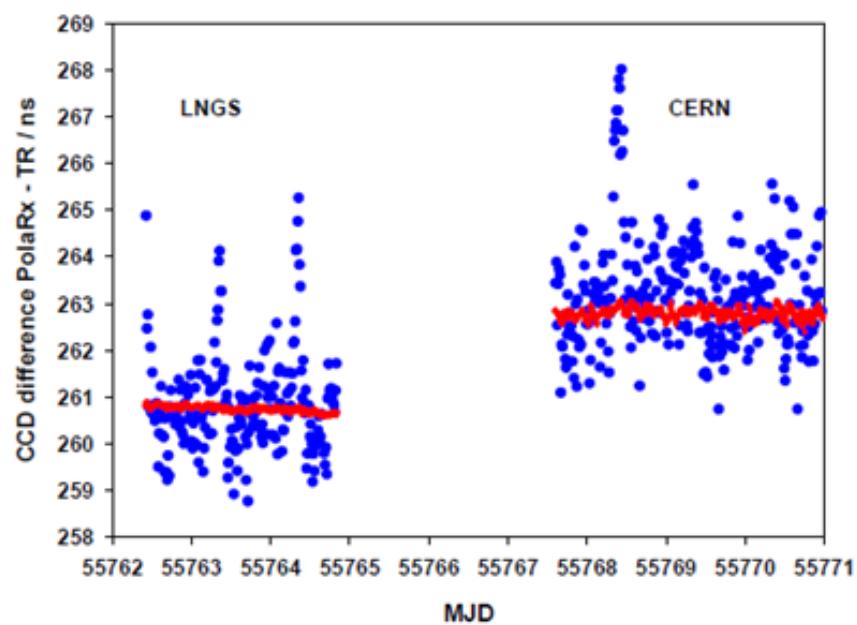

$$\delta t = (54.5 \pm 5.0 \text{ (stat.)} {}^{+9.6}_{-7.2} \text{ (sys.)}) \text{ ns}$$

# Event-by-event PDFs

## Independent twin-system calibration by the Physikalisch-Technische Bundesanstalt

High accuracy/stability portable time-transfer setup @ CERN and LNGS

GTR50 GPS receiver, thermalised, external Cs frequency source, embedded Time Interval Counter

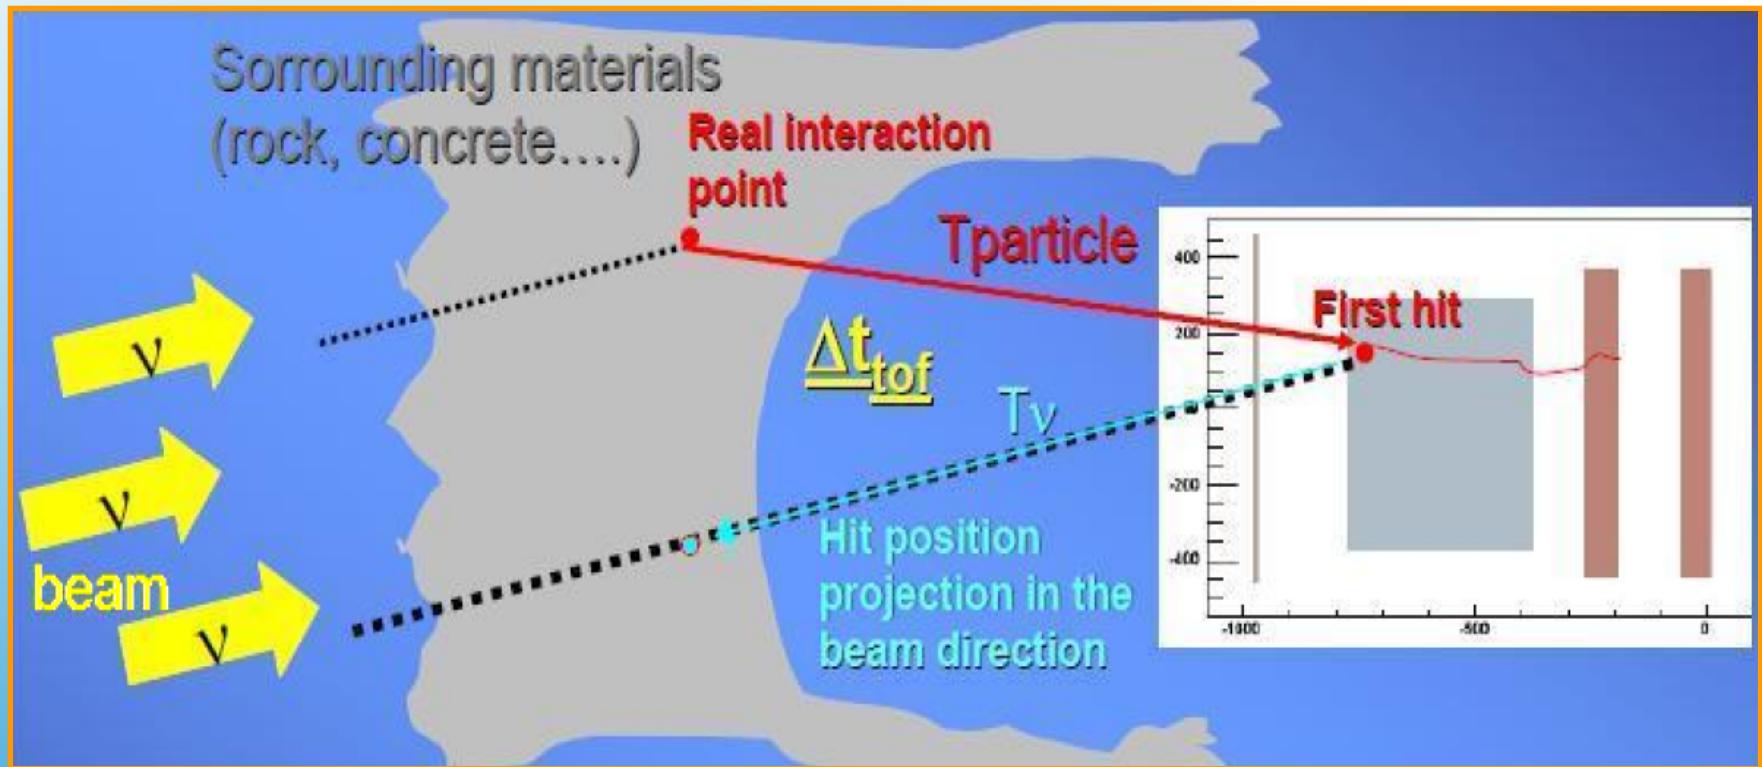

Correction to the time-link:

$$t_{\text{CERN}} - t_{\text{OPERA}} = (2.3 \pm 0.9) \text{ ns}$$

# CERN-OPERA intercalibration cross check

Item	Result	Method
CERN UTC distribution (GMT)	$10085 \pm 2$ ns	<ul style="list-style-type: none"> <li>• Portable Cs</li> <li>• Two-ways</li> </ul>
WFD trigger	$30 \pm 1$ ns	Scope
BTC delay	$580 \pm 5$ ns	<ul style="list-style-type: none"> <li>• Portable Cs</li> <li>• Dedicated beam experiment</li> </ul>
LNGS UTC distribution (fibers)	$40996 \pm 1$ ns	<ul style="list-style-type: none"> <li>• Two-ways</li> <li>• Portable Cs</li> </ul>
OPERA master clock distribution	$4262.9 \pm 1$ ns	<ul style="list-style-type: none"> <li>• Two-ways</li> <li>• Portable Cs</li> </ul>
FPGA latency, quantization curve	$24.5 \pm 1$ ns	Scope vs DAQ delay scan (0.5 ns steps)
Target Tracker delay (Photocathode to FPGA)	$50.2 \pm 2.3$ ns	UV picosecond laser
Target Tracker response (Scintillator-Photocathode, trigger time-walk, quantisation)	$9.4 \pm 3$ ns	UV laser, time walk and photon arrival time parametrizations, full detector simulation
CERN-LNGS intercalibration	$2.3 \pm 1.7$ ns	<ul style="list-style-type: none"> <li>• METAS PolaRx calibration</li> <li>• PTB direct measurement</li> </ul>

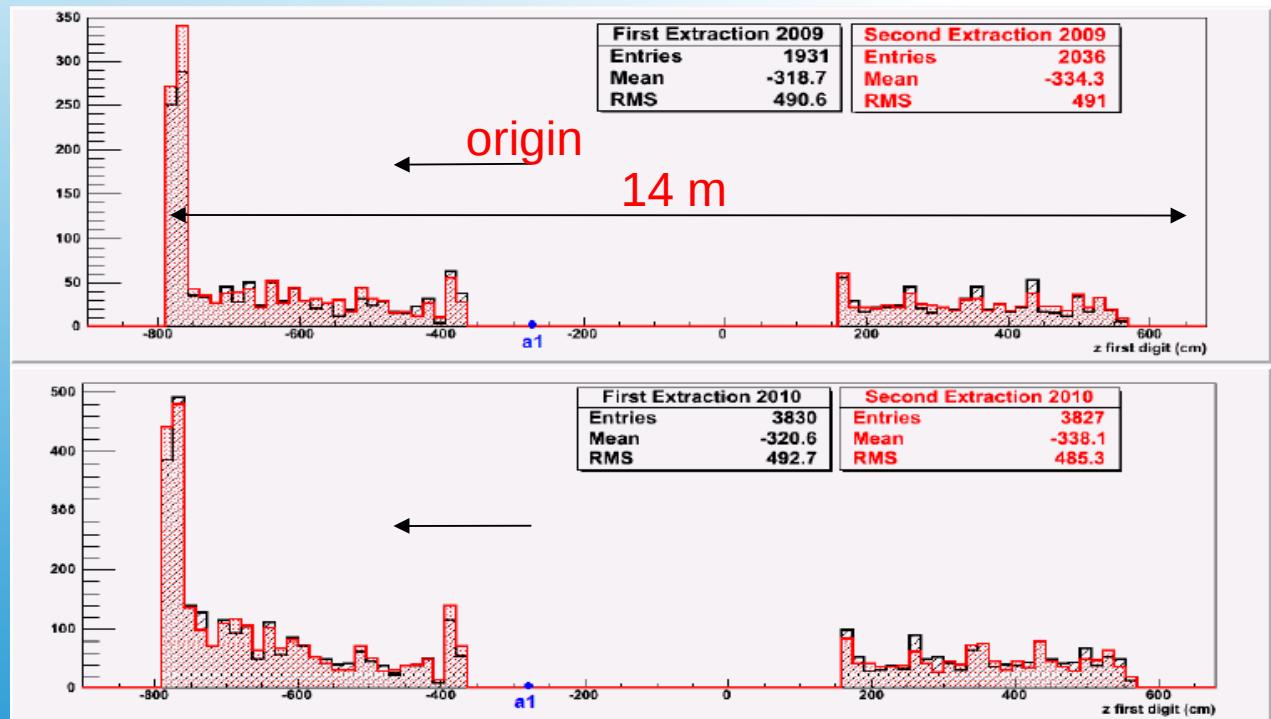

# Delay calibrations summary

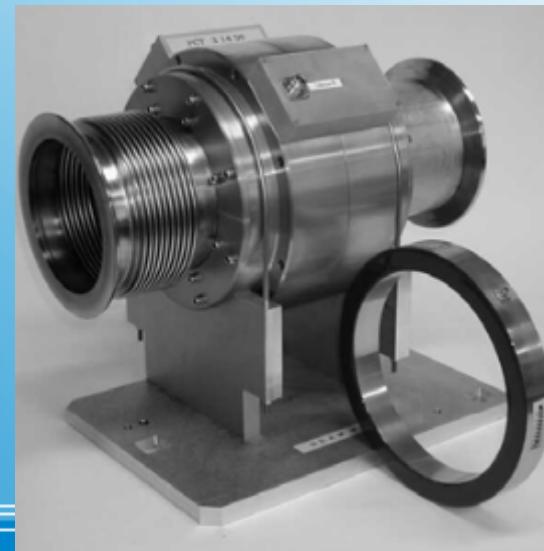

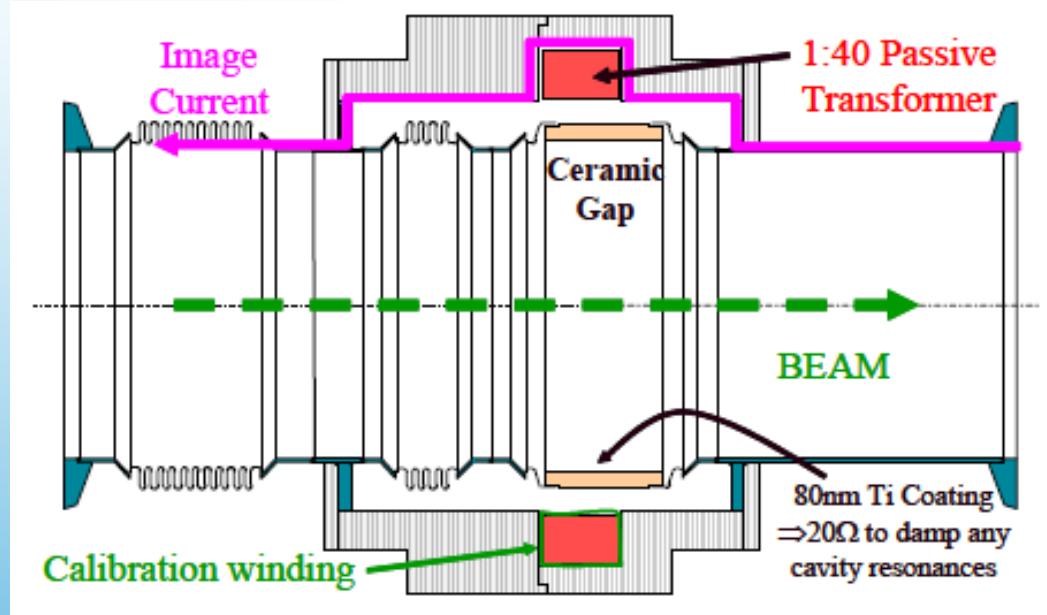

# External events

Correction due to the earliest hit position

Average correction: 140 cm  
(4.7 ns)

# Z correction

Raw BCT signal used, no integration  
<1% linearity  
Large bandwidth 400 MHz  
Low droop <0.1%/ $\mu$ s

# Fast beam current transformer

## GPS standard operation

resolves  $(x, y, z, t)$  with  $\geq 4$  satellite observations

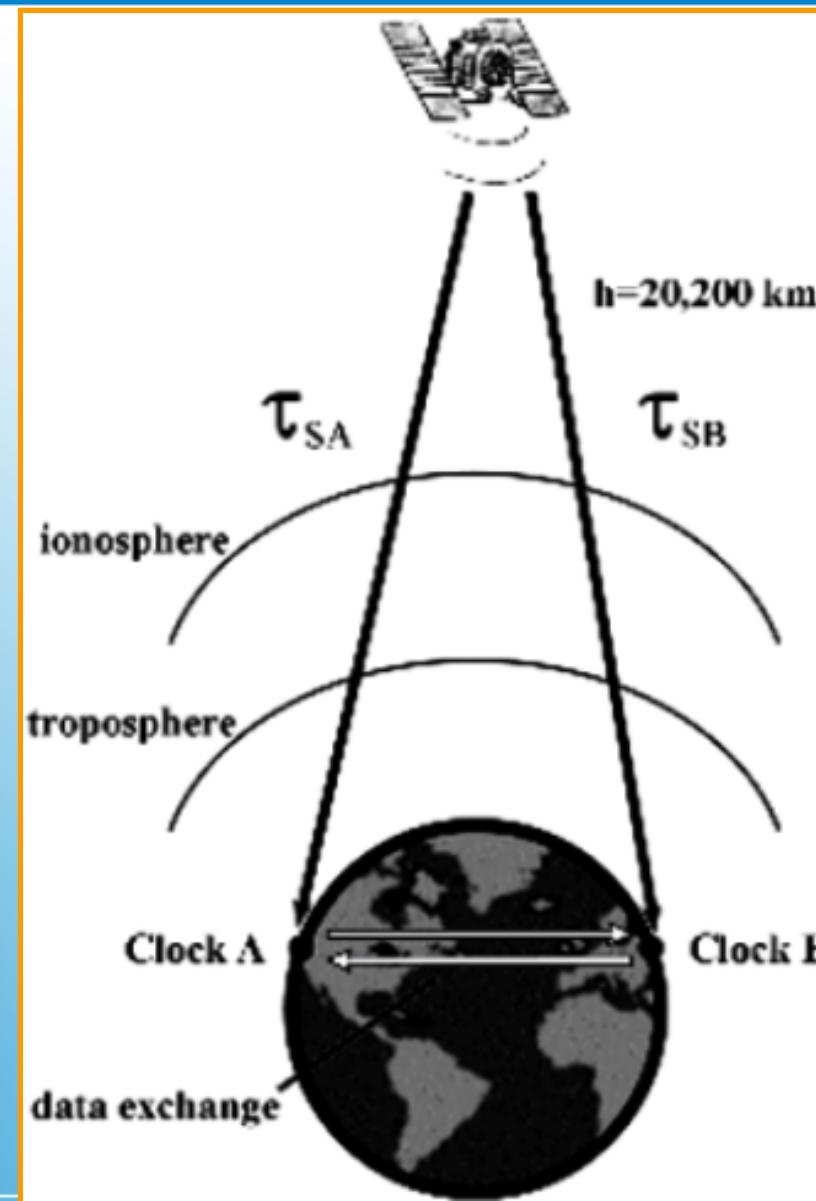

## GPS "common-view" mode

same satellite visible from two sites

Knowing  $(x, y, z)$  of the sites from former dedicated measurements  $\rightarrow$  determine time differences of local clocks w.r.t. the satellite, by off-line data exchange

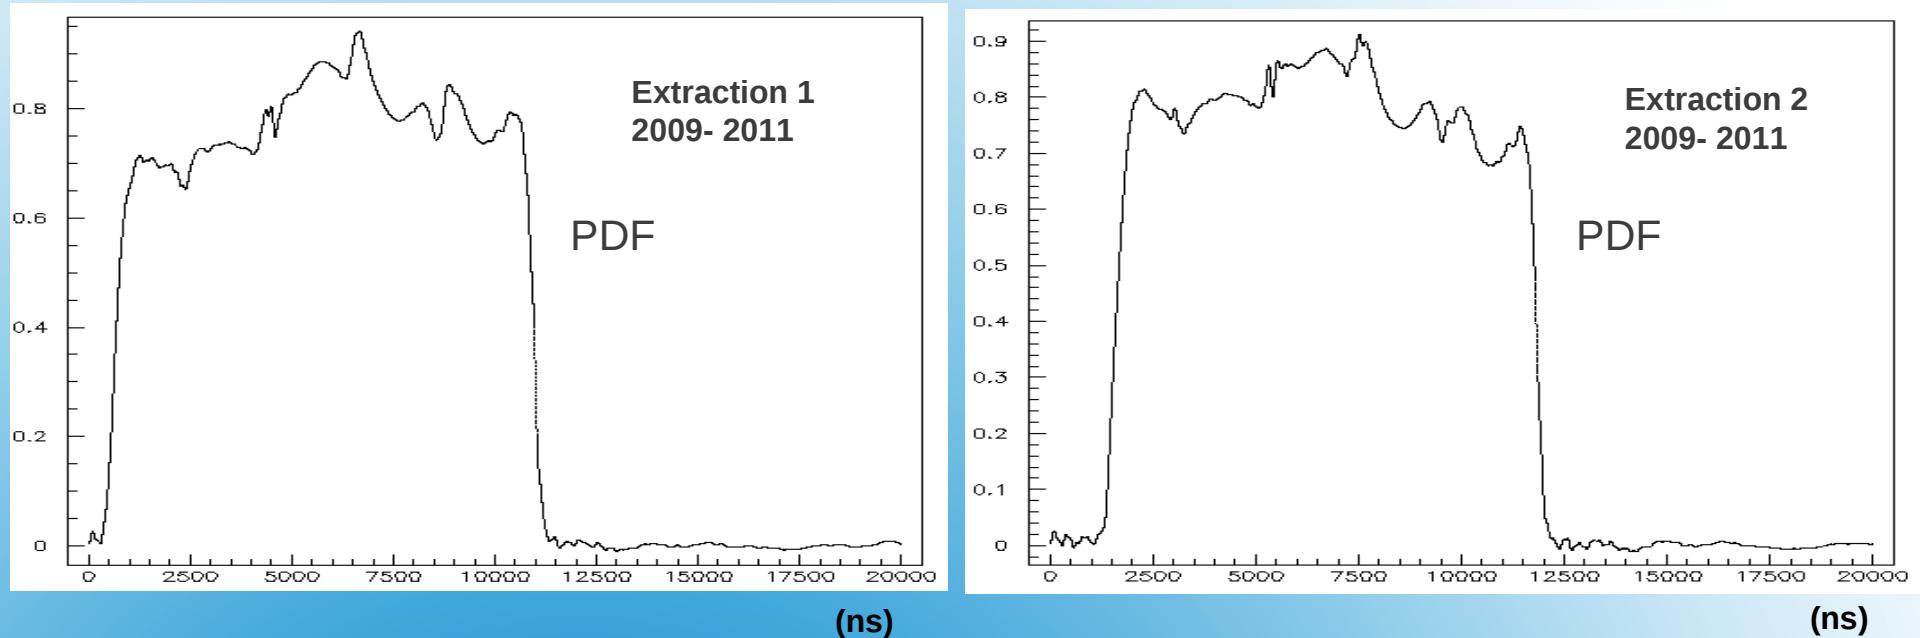

Advantage:  $730 \text{ km} \ll 20000 \text{ km}$  (satellite height)  $\rightarrow$  similar paths in ionosphere  $\rightarrow$  error cancellation

Standard technique for high accuracy t-transfer  
Permanent time link ( $\sim 1 \text{ ns}$ ) between reference points at CERN and OPERA

# GPS common view mode

- Each event is associated to its proton spill waveform
  - The “parent” proton is unknown within the  $10.5 \mu\text{s}$  extraction time
    - normalize each waveform and sum:
- Average Probability Density Function (PDF) of the predicted t-distribution of  $\nu$  events

Another approach:

→ normalize each waveform and use a different PDF for each  $\nu$  event

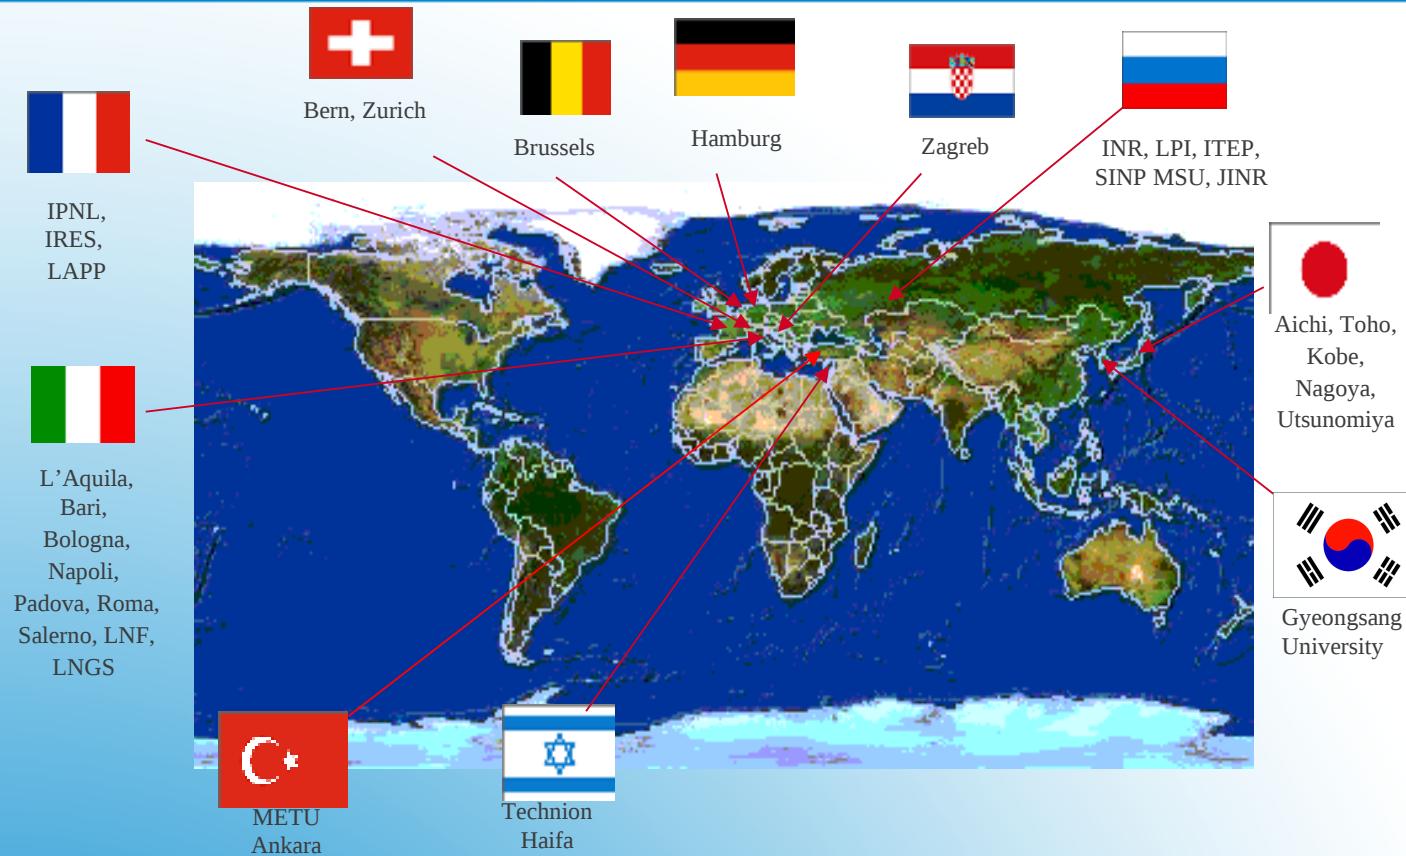

# Neutrino event-time PDF

# OPERA Coll.

- 11 countries
- 30 institutions
- 160 physicists

## Collaborators

<http://arxiv.org/pdf/1109.4897v2>

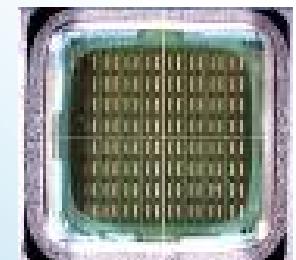

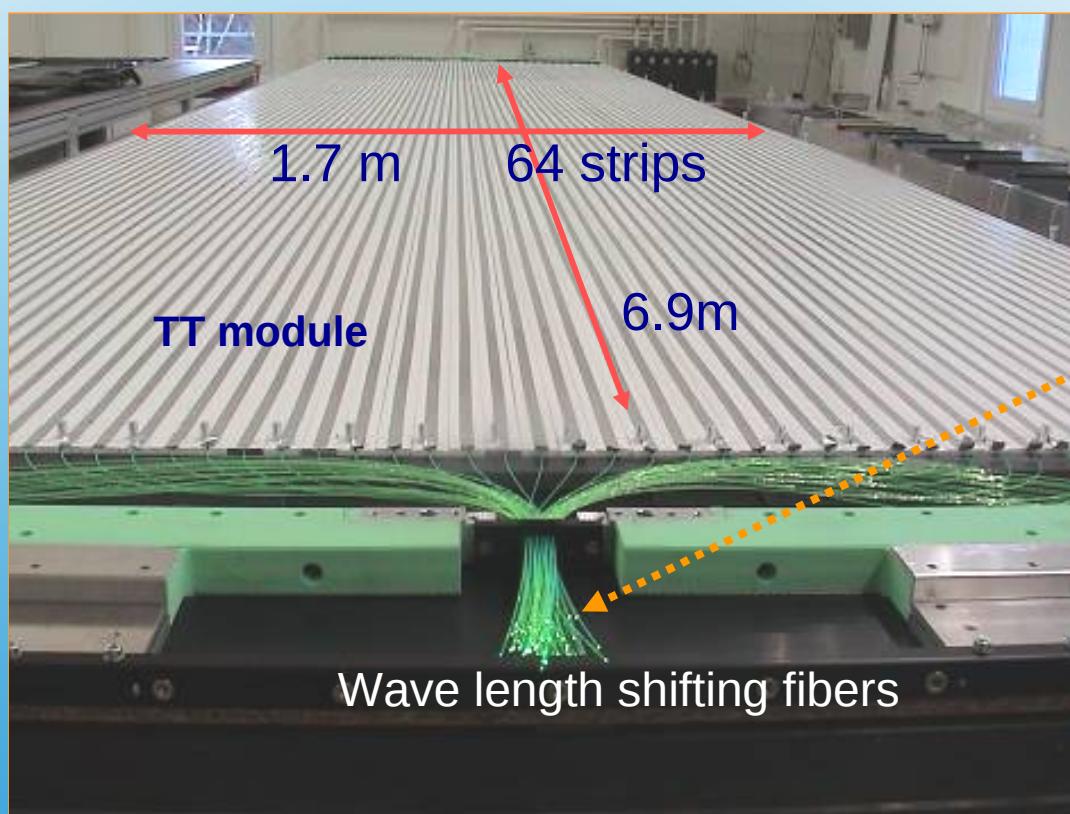

- CERN groups: CNGS beam, survey, timing and PS
- Geodesy group of the Università Sapienza of Rome
- Swiss Institute of Metrology (METAS)
- German Institute of Metrology (PTB)

# OPERA and collaborating groups

Tasks: location of the ECC containing the  $\nu$  interactions and event timing

- extruded plastic scintillator strips (2.6 cm width)
- light collections with wave length shifting fibers (WLS)
- fibers read-out at either side with multi-anode 64 pixels PMTs (H7546)

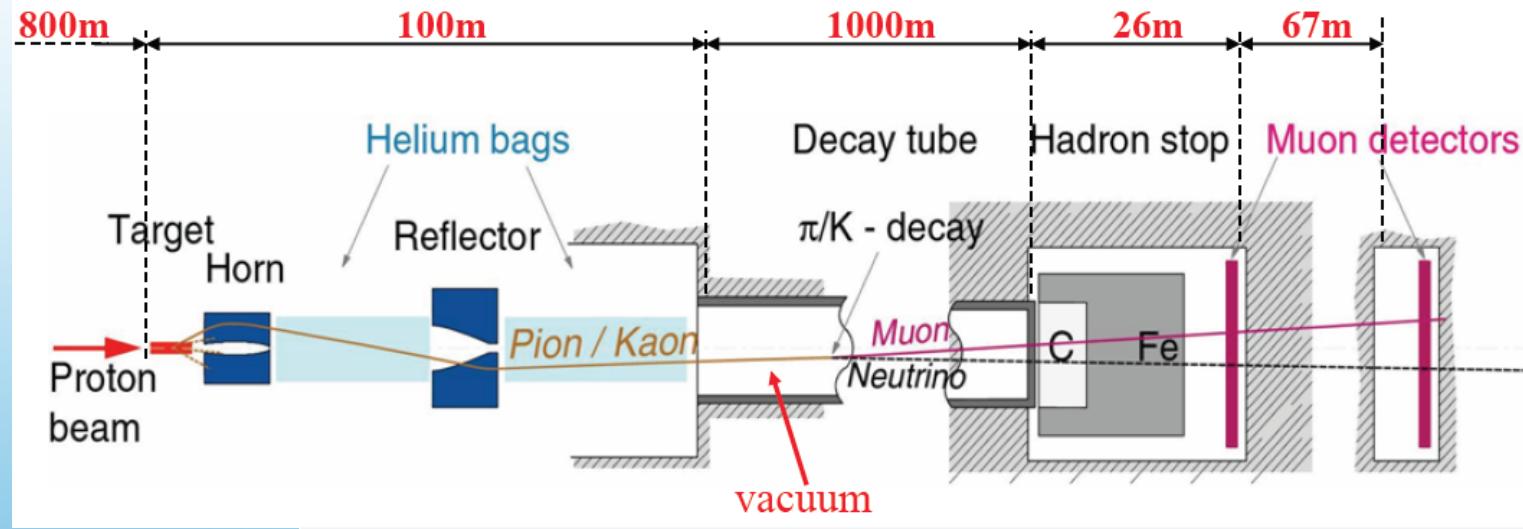

H7546  
photomultiplier

one front-end DAQ board per side

# The target tracker

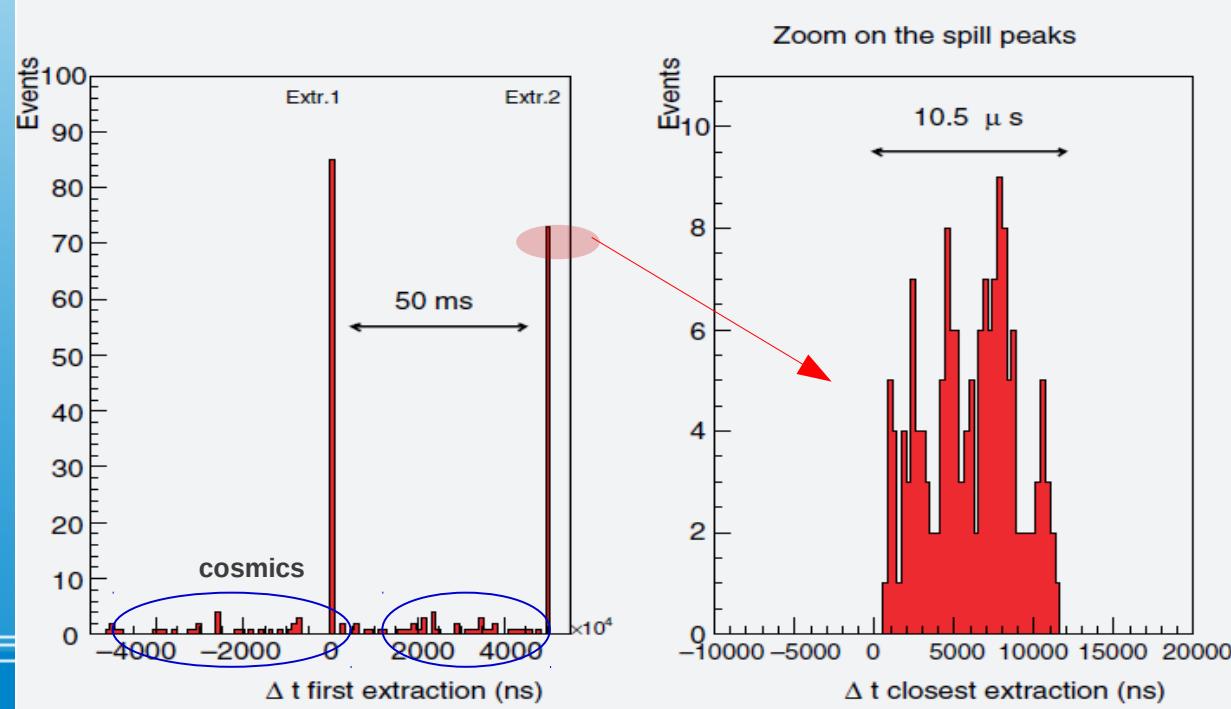

- SPS p: 400 GeV/c
- 6 s cycle
- ~ pure  $\nu_\mu$
- $\langle E_\nu \rangle = 17$  GeV traveling through the Earth's crust

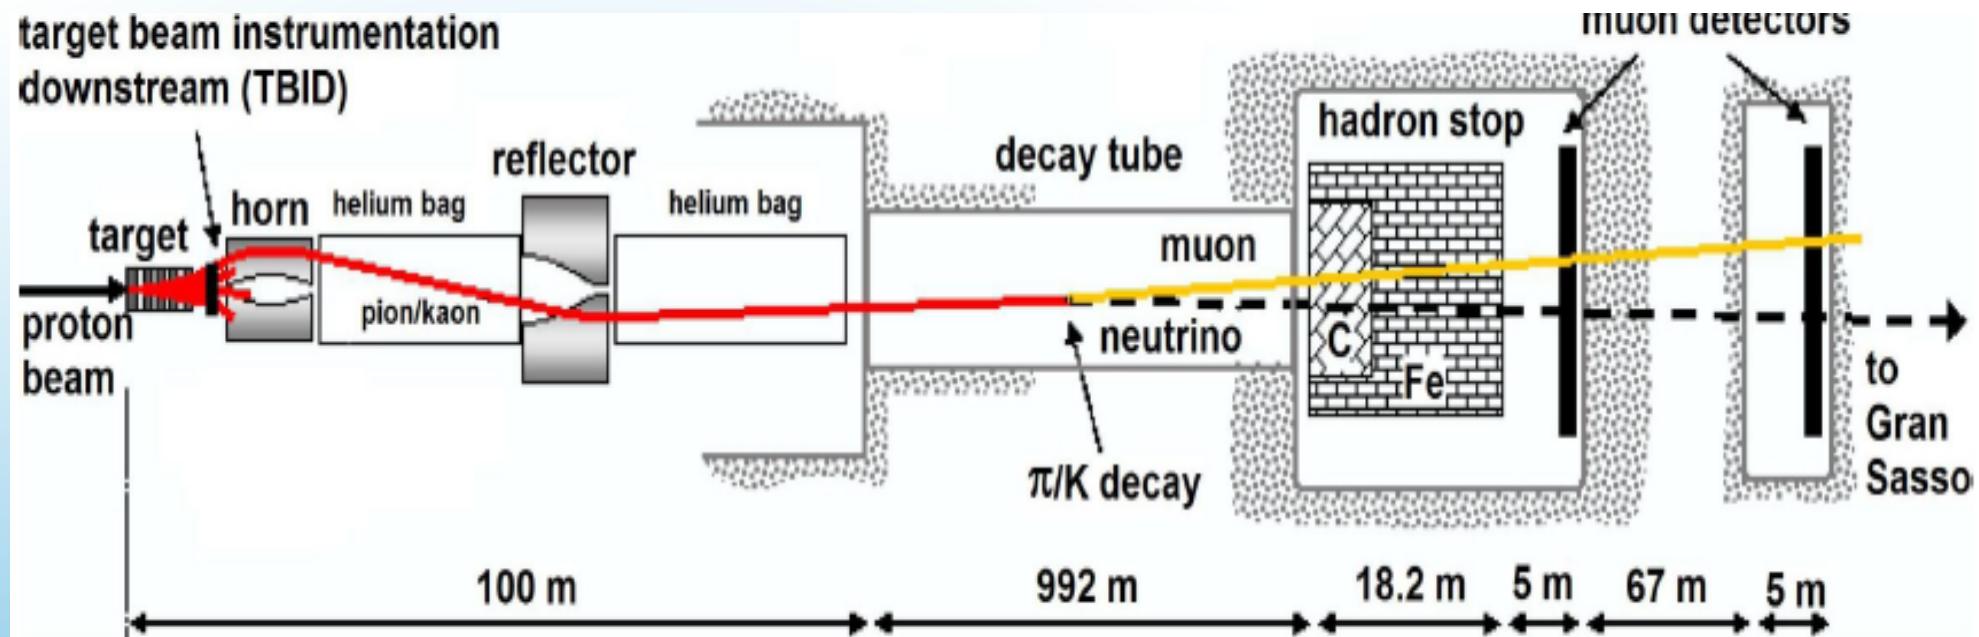

- Two  $10.5 \mu\text{s}$  extractions (by kicker magnet) separated by 50 ms

$2.4 \cdot 10^{13}$  protons/extraction

Negligible cosmic-ray background:  $O(10^{-4})$

# The CNGS neutrino beam

- $\nu$  production point is not known but:
  - accurate UTC time-stamp of protons
  - relativistic parent mesons

$\text{TOF}_c$  = assuming  $c$  from BCT to OPERA (2439280.9 ns)

$\text{TOF}_{\text{true}}$  = accounting for speed of mesons down to decay point

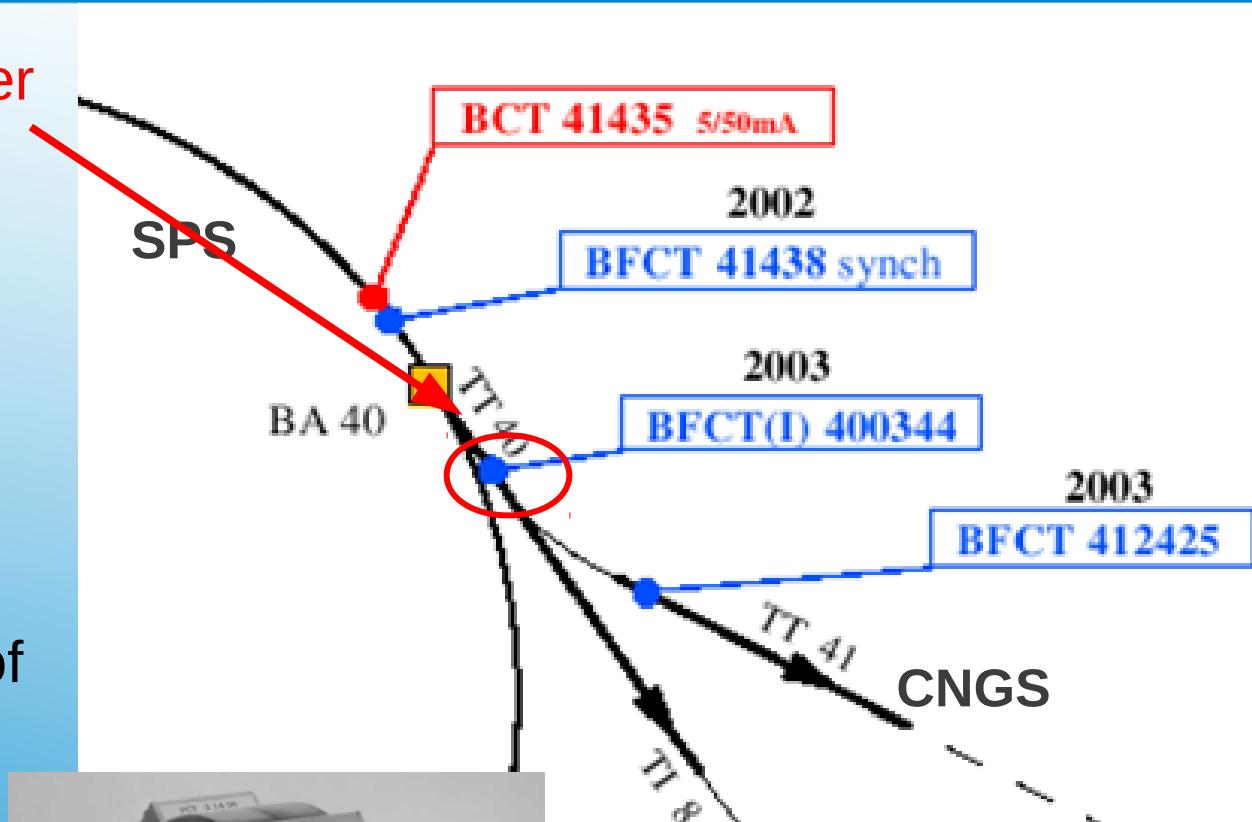

$$\Delta t = \frac{z}{\beta c} - \frac{z}{c} = \frac{z}{c} \left( \frac{1}{\beta} - 1 \right) \approx \frac{z}{c} \frac{1}{2\gamma^2}$$

$$\langle \Delta t \rangle = \text{TOF}_{\text{true}} - \text{TOF}_c = 14 \text{ ps} \quad \text{full FLUKA simulation}$$

# Neutrino production point

## Fast Beam Current Transformer ("BCT", id 400344) 400 MHz bandwidth

- Proton pulse digitized by a 1GS/s **waveform digitizer** ("WFD", Acqiris DP110)
- WFD triggered by a replica of the kicker signal
- Waveforms are **UTC time-stamped** and stored in CNGS database for offline analysis

# Accurate p timing
